(54) Title: ANTIBODY INHIBITORS OF GDF-8 AND USES THEREOF

(57) Abstract: The disclosure provides novel antibodies against growth and differentiation factor-8 (GDF-8), including antibody fragments, which inhibit GDF-8 activity *in vitro* and *in vivo*. The disclosure also provides methods for diagnosing, preventing, or treating degenerative disorders of muscle, bone, or insulin metabolism.

ANTIBODY INHIBITORS OF GDF-8

AND USES THEREOF

[001] This application claims priority to U.S. provisional patent application Serial No. 60/324,528, filed on September 26, 2001.

Field of the Invention

[002] This invention relates to inhibitors of Growth Differentiation Factor-8 (GDF-8) proteins and methods of use for such inhibitors. More particularly, the invention provides novel antibodies and antibody fragments that are specifically reactive with GDF-8 proteins *in vitro* and *in vivo*. The invention is particularly useful for diagnosing, preventing, or treating human or animal disorders in which an increase in muscle tissue would be therapeutically beneficial. Exemplary disorders include neuromuscular disorders (*e.g.*, muscular dystrophy and muscle atrophy), congestive obstructive pulmonary disease, muscle wasting syndrome, sarcopenia, and cachexia; adipose tissue disorders (*e.g.*, obesity); type 2 diabetes; and bone degenerative disease (*e.g.*, osteoporosis).

Background of the Invention

[003] Growth and Differentiation Factor-8 (GDF-8), also known as myostatin, is a member of the Transforming Growth Factor-beta (TGF-β) superfamily of structurally related growth factors, all of which possess physiologically important growth-regulatory and morphogenetic properties (Kingsley *et al.* (1994) *Genes Dev.*, 8: 133-46; Hoodless *et al.* (1998) *Curr. Topics Microbiol.*

Immunol., 228: 235-72). GDF-8 is a negative regulator of skeletal muscle mass, and there is considerable interest in identifying factors which regulate its biological activity. For example, GDF-8 is highly expressed in the developing and adult skeletal muscle. The GDF-8 null mutation in transgenic mice is characterized by a marked hypertrophy and hyperplasia of the skeletal muscle (McPherron *et al.* (1997) *Nature,* 387: 83-90). Similar increases in skeletal muscle mass are evident in naturally occurring mutations of GDF-8 in cattle (Ashmore *et al.* (1974) *Growth,* 38: 501-507; Swatland and Kieffer (1994) *J. Anim. Sci.,* 38: 752-757; McPherron and Lee (1997) *Proc. Natl. Acad. Sci. USA,* 94: 12457-12461; and Kambadur *et al.* (1997) *Genome Res.,* 7: 910-915). Since GDF-8 is expressed in both developing and adult muscles, it is not clear whether it regulates muscle mass during development or in adults. Thus, the question of whether or not GDF-8 regulates muscle mass in adults is important from a scientific and therapeutic perspective. Recent studies have also shown that muscle wasting associated with HIV-infection in humans is accompanied by increases in GDF-8 protein expression (Gonzalez-Cadavid *et al.* (1998) *PNAS,* 95: 14938-43). In addition, GDF-8 can modulate the production of muscle-specific enzymes (*e.g.,* creatine kinase) and modulate myoblast cell proliferation (WO 00/43781).

[004] A number of human and animal disorders are associated with loss or functional impairment of muscle tissue, including muscular dystrophy, muscle atrophy, congestive obstructive pulmonary disease, muscle wasting syndrome, sarcopenia, and cachexia. To date, very few reliable or effective

therapies exist for these disorders. However, the terrible symptoms associated with these disorders may be substantially reduced by employing therapies that increase the amount of muscle tissue in patients suffering from the disorders. While not curing the conditions, such therapies would significantly improve the quality of life for these patients and could ameliorate some of the effects of these diseases. Thus, there is a need in the art to identify new therapies that may contribute to an overall increase in muscle tissue in patients suffering from these disorders.

[005] In addition to its growth-regulatory and morphogenetic properties in skeletal muscle, GDF-8 may also be involved in a number of other physiological processes, including glucose homeostasis in the development of type 2 diabetes and adipose tissue disorders, such as obesity. For example, GDF-8 modulates preadipocyte differentiation to adipocytes (Kim *et al.* (2001) *BBRC,* 281: 902-906).

[006] There are also a number of conditions associated with a loss of bone, including osteoporosis, especially in the elderly and/or postmenopausal women. Currently available therapies for these conditions work by inhibiting bone resorption. A therapy that promotes new bone formation would be a desirable alternative to or addition to, these therapies.

[007] Like TGF-β-1, -2, and -3, the GDF-8 protein is synthesized as a precursor protein consisting of an amino-terminal propeptide and a carboxy-terminal mature domain (McPherron and Lee, (1997) *Proc. Natl. Acad. Sci. USA,* 94: 12457-12461). Before cleavage, the precursor GDF-8

protein forms a homodimer. The amino-terminal propeptide is then cleaved

from the mature domain. The cleaved propeptide may remain noncovalently

bound to the mature domain dimer, inactivating its biological activity

(Miyazono *et al.* (1988) *J. Biol. Chem.*, 263: 6407-6415; Wakefield *et al.*

(1988) *J. Biol. Chem.*, 263: 7646-7654; and Brown *et al.* (1990) *Growth*

Factors, 3: 35-43). It is believed that two GDF-8 propeptides bind to the

GDF-8 mature dimer (Thies *et al.* (2001) *Growth Factors*, 18: 251-259). Due

to this inactivating property, the propeptide is known as the

"latency-associated peptide" (LAP), and the complex of mature domain and

propeptide is commonly referred to as the "small latent complex" (Gentry and

Nash (1990) *Biochemistry*, 29: 6851-6857; Derynck *et al.* (1995) *Nature*, 316:

701-705; and Massague (1990) *Ann. Rev. Cell Biol.*, 12: 597-641). Other

proteins are also known to bind to GDF-8 or structurally related proteins and

inhibit their biological activity. Such inhibitory proteins include follistatin, and

potentially, follistatin-related proteins (Gamer *et al.* (1999) *Dev. Biol.*, 208:

222-232). The mature domain is believed to be active as a homodimer when

the propeptide is removed.

[008] GDF-8 is highly conserved in sequence and in function across species.

The amino acid sequence of murine and human GDF-8 is identical, as is the

pattern of mRNA expression (McPherron *et al.* (1997) *Nature* 387: 83-90;

Gonzalez-Cadavid *et al.* (1998) *Proc. Natl. Acad. Sci. USA* 95: 14938-14943).

This conservation of sequence and function suggests that inhibition of GDF-8

in humans is likely to have a similar effect to inhibition of GDF-8 in mice.

[009] GDF-8 is involved in the regulation of many critical biological

processes. Due to its key function in these processes, GDF-8 may be a

desirable target for therapeutic intervention. In particular, therapeutic agents

that inhibit the activity of GDF-8 may be used to treat human or animal

disorders in which an increase in muscle tissue would be therapeutically

beneficial, particularly muscle and adipose tissue disorders, bone

degenerative diseases, neuromuscular disorders, and diabetes, as discussed

above.

Summary of the Invention

[010] The present invention provides novel protein inhibitors comprising

antibodies and antibody fragments that are specifically reactive with a mature

GDF-8 protein, whether it is in a monomeric form, active dimeric form, or

complexed in the GDF-8 latent complex. In an embodiment of the invention,

the antibodies bind to an epitope on the mature GDF-8 protein, which results

in a reduction in one or more of the biological activities associated with

GDF-8, relative to a mature GDF-8 protein that is not bound by the same

antibody. In an embodiment of the invention, the presently disclosed

antibodies reduce GDF-8 activity associated with negative regulation of

skeletal muscle mass and/or bone density.

[011] The presently disclosed antibodies possess unique and unexpected

biological properties. For instance, one of skill in the art would typically

expect good neutralizing antibodies to strongly bind to the active GDF-8

protein *in vitro*, forming a stable inhibitory complex with the protein. A

neutralizing antibody also called an inhibitory antibody, having a high affinity for a particular protein will typically be expected to provide higher levels of neutralization relative to a lower affinity antibody to the same protein. However, quite unexpectedly, the present inventors have discovered antibodies that only weakly bind to and neutralize active GDF-8 protein *in vitro*, yet are effective *in vivo*. The discovery of such antibodies led, in turn, to the identification of a specific site on GDF-8 to which the antibodies bind. It is therefore expected that any antibody specifically binding to the identified site would similarly possess *in vivo* neutralizing properties.

[012] Additionally, the presently disclosed antibodies possess unique and unexpected properties. For example, the antibodies not only recognize mature GDF-8 protein in its monomeric and dimeric forms, but also recognize the intact GDF-8 latent complex.

[013] The presently disclosed antibodies may be administered in a therapeutically effective dose to treat or prevent medical conditions in which an increase in muscle tissue mass or bone density would be therapeutically beneficial. Diseases and disorders that may be treated by these GDF-8 antibodies include muscle or neuromuscular disorders such as muscular dystrophy, muscle atrophy, congestive obstructive pulmonary disease, muscle wasting syndrome, sarcopenia, and cachexia; adipose tissue disorders such as obesity; metabolic disorders such as type 2 diabetes, impaired glucose tolerance, metabolic syndromes (*e.g.*, syndrome X), insulin resistance induced by trauma (*e.g.*, burns); and bone degenerative disease such as

osteoporosis, especially in the elderly and/or postmenopausal women. Additional metabolic bone diseases and disorders amenable to treatment with these GDF-8 antibodies include low bone mass due to chronic glucocorticoid therapy, premature gonadal failure, androgen suppression, vitamin D deficiency, secondary hyperparathyroidism, nutritional deficiencies, and anorexia nervosa.

[014] In addition, the presently disclosed antibodies may be used as a diagnostic tool to quantitatively or qualitatively detect mature GDF-8 protein or fragments thereof, regardless of whether it is in a monomeric form, dimeric active form, or complexed in the GDF-8 latent complex. For example, the antibodies may be used to detect quantitatively or qualitatively mature GDF-8 protein in a cell, bodily fluid, tissue, or an organ. The presence or amount of mature GDF-8 protein detected is then correlated with one or more of the medical conditions listed above.

[015] The presently disclosed antibodies may be provided in a diagnostic kit. The kit may contain other components that aid the detection of mature GDF-8 protein, and help correlate the results with one or more of the medical conditions described above.

Brief Description of the Sequences

SEQ ID NO.	Figure (if applicable)	Description
1	Figure 16	JA-16 heavy chain variable region AA sequence
2, 3, 5, 8		Antibody binding sites in protein
4		DNA sequence for GDF-8 (accession no. xm_030768)
6		Nucleic acid sequence encoding SEQ ID NO: 1
7		DNA sequence for BMP-11 (accession no. xm_049170)
9		B1 peptide, derived from BMP-11
10		G1 peptide, derived from GDF-8
11-13, 65, 105, 114, 129	Figure 1	Synthetic peptides derived from SEQ ID NO:14
14		A cysteine-to-serine mutated sequence of mature GDF-8.
15	Figure 3	mature GDF-8 AA sequence
16	Figure 3	BMP-11 AA sequence
18		JA-16 eptitope region from GDF-8
17-64	Figure 6A	Overlapping 13-mer peptides corresponding to portions of the GDF-8 sequence
65		Biotinylated N-terminal peptide derived from GDF-8
66-104, 106-113, 115-128		Mutated versions of SEQ ID NO:18
130		AA sequence of GDF-8 propeptide (accession no. xp_030768)
131		AA sequence of BMP-11 propeptide (accession no. xp_049170)

Brief Description of the Figures

[016]   Fig. 1 shows the GDF-8 synthetic peptides (SEQ ID NOS: 11-13, 65, 105, 114, and 129, all derived from SEQ ID NO:14) used to characterize the binding specificity of JA-16. The underlined amino acids indicate positions where native cysteines have been replaced with serines.

[017]   Fig. 2 shows the binding of JA-16 to the GDF-8 synthetic peptides.

[018] Fig. 3 indicates the differences in the amino acid sequences of mature

GDF-8 (SEQ ID NO:15) and BMP-11 (SEQ ID NO:16).

[019] Fig. 4 shows a comparison of the binding characteristics of JA-16 to G1

peptide (SEQ ID NO:10, a peptide derived from GDF-8) conjugated to bovine

serum albumin (BSA) and B1 peptide (SEQ ID NO:9, a peptide derived from

BMP-11) conjugated to BSA.

[020] Fig. 5 shows a comparison of the binding characteristics of JA-16 to

G1-BSA (SEQ ID NO:10) after JA-16 is preincubated with G1, B1, GDF-8, or

BMP-11.

[021] Figs. 6A and B show the mapping studies of JA-16 binding using

overlapping 13-mer synthetic peptide sequences from GDF-8.

[022] Fig. 7A and B show the results of a deletion and substitution analysis of

the JA-16 epitope region from GDF-8,

Gly-Leu-Asp-Ser-Asp-Glu-His-Ser-Thr-Glu-Ser-Arg-Ser (SEQ ID NO:18),

using spot synthesis.

[023] Fig. 8 shows the binding of biotinylated GDF-8 to the ActRIIB receptor.

[024] Fig. 9A and 9B show the inhibition of biotinylated GDF-8 binding to the

ActRIIB receptor in the presence and absence of JA-16.

[025] Fig. 10 shows a reporter gene assay assessing the neutralizing effect

of JA-16 on the activity of GDF-8 *in vitro*.

[026]   Fig. 11 shows the *in vivo* effect of JA-16 in mice during a 4 week study.

Seven week-old female BALB/c mice were treated for four weeks with JA-16

by intraperitoneal injection at 50 mg/kg twice weekly. The graph on the left

shows the change in lean and fat mass during the treatment period as

measured by dexascan (dual energy x-ray) analysis. The graph on the right

shows the mass of dissected tissues. A statistically significant difference,

$p < 0.01$ for a student test, is indicated by an asterisk.

[027]   Fig. 12 shows the *in vivo* effect of JA-16 on total body mass of mice

during a 14-week study. Male C57BL mice used in this study were either wild

type at the agouti locus (a) or carried the lethal yellow mutation (Ay) at that

locus. The Ay mutation causes adult onset obesity and diabetes. Young

adult mice were treated with weekly intraperitoneal injections of 60 mg/kg of

JA-16 or control antibody. In addition, at the start of the treatment period,

mice were loaded with 60 mg/kg intraperitoneally and 10 mg/kg intravenously

of the same antibody. These graphs show the weekly body weight for each

group of mice. The error bars show the standard error of the mean for each

data point.

[028]   Fig. 13 shows the *in vivo* effect of JA-16 on total muscle mass in mice

during a 14 week study. At the end of the study, muscles were dissected and

weighed. These graphs show the average muscle mass for each group of

mice. A statistically significant difference, $p < 0.01$ for a student test, is

indicated by an asterisk.

[029]   Fig. 14 shows the *in vivo* effect of JA-16 on total fat mass in mice during a 14-week study. At the end of the study, fat pads were dissected and weighed. These graphs show the average fat pad mass for each group of mice.

[030]   Fig. 15 shows the *in vivo* effect of JA-16 on blood glucose levels in mice during a 14 week study. After 12 weeks of treatment, the C57BL-Ay/a mice were fasted overnight and their blood glucose was measured.

[031]   Fig. 16 shows the amino acid sequence of the JA-16 heavy chain variable region (SEQ ID NO:1). The complimentarity determining regions (CDRs) are underlined. The corresponding nucleic acid sequence is provided in SEQ ID NO:6.

[032]   Fig. 17 shows an *in vivo* comparison of Myo-19 and JA-16. Seven week-old female C57B6/scid mice were treated for five weeks with JA-16, Myo-19, or vehicle by intraperitoneal injection. At the end of the study, muscles were dissected and weighed. These graphs show the average muscle mass for each group of mice. A statistically significant difference, $p<0.01$ for a student t-test, is indicated by an asterisk.

[033]   Fig. 18 shows results from the immunoprecipitation of GDF-8 with JA-16 and Myo-19.

[034]   Figs. 19A and 19B show results of JA-16 treatment in BALB/c female mice for eight weeks. Mice were 21 months or 4 months of age at the end of the study. (19A) Dissected quadriceps mass for JA-16 treated and vehicle

treated mice at the end of the study. (19B) Forelimb strength determined by a grip test for JA-16 treated and vehicle treated mice after seven weeks of treatment. Each bar or data point indicates the average value for the indicated group ± the standard error; (**) indicates that $p < 0.01$ for Student's t-test comparing the JA-16 group to the vehicle group; n = 8 for each group.

[035] Figs. 20A-20D show results of JA-16 treatment in *mdx* mice. (20A) JA-16 treated mice had significantly increased EDL weight compared to *mdx* controls (19.72±0.50 vs. 14.63 ± 0.69 mg; n=12; p<0.0001). (20B) JA-16 treated mice had significantly increased muscle mass to body weight ratio (EDL weight / body weight) as compared to control (0.6 ± 0.02 vs. 0.5 ± 0.02; n=12; p<0.014). (20C) JA-16 treated mice generated significantly greater force during isometric twitch contraction as compared to control (177.32 ± 8.37 vs. 132.38 ± 12.45 mN; n=12; p<0.03). (20D) JA-16 treated mice generated significantly greater force during isometric tetanic contraction compared to control (491.23 ± 16.34 vs. 370.74 ± 19.21 mN; n=12; p<0.003).

Definitions

[036] The term "antibody" refers to one or more polyclonal antibodies, monoclonal antibodies, antibody compositions, antibodies having mono- or poly-specificity, humanized antibodies, single-chain antibodies, chimeric antibodies, CDR-grafted antibodies, antibody fragments such as Fab, F(ab')$_2$, Fv, and other antibody fragments which retain the antigen binding function of the parent antibody.

[037] The term "chimeric antibodies" refers to molecules in which a portion of the heavy and/or light chain is identical or homologous to corresponding sequences from a particular species (or belonging to a particular antibody class or subclass), while the remainder of the chain(s) is identical or homologous to corresponding sequences derived from a different species (or belonging to a different antibody class or subclass). Such chimeric antibodies are described by Morrison, et al. (1984) *Proc. Natl. Acad. Sci. USA* 81: 6851-6855.

[038] The term "epitope" refers to a molecule or portion of a molecule that is capable of specifically reacting with an anti-GDF-8 monoclonal antibody. Epitopes may comprise proteins, protein fragments, peptides, carbohydrates, lipids, or other molecules, but are most commonly proteins, short oligopeptides, or combinations thereof.

[039] The terms "GDF polypeptide" and "GDF protein" refer generally to any growth and differentiation factors that are structurally or functionally related to GDF-8.

[040] The term "GDF inhibitor" includes any agent capable of inhibiting activity, expression, processing, or secretion of a GDF protein. Such inhibitors include proteins, antibodies, peptides, peptidomimetics, ribozymes, anti-sense oligonucleotides, double-stranded RNA, and other small molecules which specifically inhibit the GDF proteins.

[041] The terms "GDF-8" or "GDF-8 protein" refer to a specific growth and differentiation factor. The terms include the full length unprocessed precursor form of the protein, as well as the mature and propeptide forms resulting from post-translational cleavage. The terms also refer to any fragments of GDF-8 that maintain the known biological activities associated with the protein, as discussed herein, including sequences that have been modified with conservative or non-conservative changes to the amino acid sequence.

[042] These GDF-8 molecules may be derived from any source, natural or synthetic. The human form of mature GDF-8 protein is provided in SEQ ID NO:15. However, the present invention also encompasses GDF-8 molecules from all other sources, including GDF-8 from bovine, chicken, murine, rat, porcine, ovine, turkey, baboon, and fish. These various GDF-8 molecules have been described in McPherron *et al.* (1997) *Proc. Natl. Acad. Sci. USA*, 94: 12457-12461.

[043] "Mature GDF-8" refers to the protein that is cleaved from the carboxy-terminal domain of the GDF-8 precursor protein. The mature GDF-8 may be present as a monomer, homodimer, or in a GDF-8 latent complex. Depending on the *in vivo* or *in vitro* conditions, an equilibrium between any or all of these different forms may exist. GDF-8 is believed to be biologically active as homodimer. In its biologically active form, the mature GDF-8 is also referred to as "active GDF-8."

[044] "GDF-8 propeptide" refers to the polypeptide that is cleaved from the amino-terminal domain of the GDF-8 precursor protein. The GDF-8

propeptide is capable of binding to the propeptide binding domain on the mature GDF-8.

[045] "GDF-8 latent complex" refers to the complex of proteins formed between the mature GDF-8 homodimer and the GDF-8 propeptide. It is believed that two GDF-8 propeptides associate with a GDF-8 homodimer to form an inactive tetrameric complex. The latent complex may include other GDF-8 inhibitors in place of or in addition to one or more of the GDF-8 propeptides.

[046] The phrase "GDF-8 inhibitor" includes any agent capable of inhibiting the activity, expression, processing, or secretion of GDF-8 protein. Such inhibitors include proteins, antibodies, peptides, peptidomimetics, ribozymes, anti-sense oligonucleotides, double-stranded RNA, and other small molecules that specifically inhibit the activity of GDF-8 protein. Such inhibitors are said to "neutralize" or "reduce" the biological activity of GDF-8 protein.

[047] The phrase "GDF-8 activity" refers to one or more of growth-regulatory or morphogenetic activities associated with active GDF-8 protein. For example, active GDF-8 is a negative regulator of skeletal muscle. Active GDF-8 can also modulate the production of muscle-specific enzymes (e.g., creatine kinase), stimulate myoblast cell proliferation, and modulate preadipocyte differentiation to adipocytes.

[048] The terms "isolated" or "purified" refer to a molecule that is substantially free of its natural environment. For instance, an isolated protein is

substantially free of cellular material or other contaminating proteins from the

cell or tissue source from which it is derived. The phrase "substantially free of

cellular material" refers to preparations where the isolated protein is at least

70% to 80% (w/w) pure, optionally at least 80%-89% (w/w) pure, optionally

90-95% pure; and optionally at least 96%, 97%, 98%, 99% or 100% (w/w)

pure.

[049] "Mammal" for purposes of treatment refers to any animal classified as a

mammal, including humans, domestic and farm animals, and zoo, sports, or

pet animals, such as dogs, horses, cats, sheep, pigs, cows, *etc*. The mammal

is human in one embodiment of the invention.

[050] The term "monoclonal antibody" refers to one or more antibodies from

a substantially homogeneous antibody population that is directed against a

single antigenic epitope. The term encompasses humanized antibodies,

single-chain antibodies, chimeric antibodies, CDR-grafted antibodies,

antibody fragments such as Fab, F(ab')$_2$, Fv, and other antibody fragments

which retain the antigen binding function of the parent antibody.

[051] Furthermore, the term "monoclonal antibody" is not limited to any

particular species or source of the antibody, or the manner by which it is

made. Monoclonal antibodies may be made via traditional hybridoma

techniques (Kohler and Milstein (1975) *Nature,* 256: 495-499), recombinant

DNA methods (U.S. Pat. No. 4,816,567), or phage antibody libraries

(Clackson *et al.* (1991) *Nature,* 352: 624-628; Marks *et al.* (1991) *J. Mol. Biol.,*

222: 581-597). Monoclonal antibodies of any mammalian or non-mammalian

species can be used in this invention. For example, the antibodies may be derived from primates (*e.g.*, human, orangutan, etc.), avian (*e.g.*, chicken, turkey, etc.), bovine, murine, rat, porcine, ovine, or fish. In one embodiment of the invention, the antibodies are of rat, murine, or human origin.

[052] The terms "neutralize" and "neutralizing" refer to a reduction in the activity of GDF-8 by a GDF-8 inhibitor, relative to the activity of a GDF-8 molecule that is not bound by the same inhibitor. Thus, a "neutralizing" antibody reduces the activity of GDF-8 relative to the activity of a GDF-8 molecule not bound by the same antibody. The activity of the GDF-8 protein, when bound by one or more of the presently disclosed GDF-8 inhibitors (*e.g.*, the presently disclosed antibodies), is reduced at least about 10%, 15%, 20%, 25%, 30%, 35%, 40%, 45%, 50%, or 55%, optionally at least about 60%, 62%, 64%, 66%, 68%, 70%, 72%, 72%, 76%, 78%, 80%, 82%, 84%, 86%, or 88%, optionally at least about 90%, 91%, 92%, 93%, or 94%, and optionally at least 95% to 100% relative to a GDF-8 protein that is not bound by one or more of the presently disclosed GDF-8 inhibitors.

[053] The term "specific interaction," or "specifically binds," or the like, means that two molecules form a complex that is relatively stable under physiologic conditions. The term is also applicable where, *e.g.*, an antigen-binding domain is specific for a particular epitope, which is carried by a number of antigens, in which case the specific binding member carrying the antigen-binding domain will be able to bind to the various antigens carrying the epitope. Specific binding is characterized by a high affinity and a low to

moderate capacity. Nonspecific binding usually has a low affinity with a moderate to high capacity. Typically, the binding is considered specific when the affinity constant K_a is higher than $10^6 M^{-1}$, or can be higher than $10^8 M^{-1}$. If necessary, non-specific binding can be reduced without substantially affecting specific binding by varying the binding conditions. Such conditions are known in the art, and a skilled artisan using routine techniques can select appropriate conditions. The conditions are usually defined in terms of concentration of antibodies, ionic strength of the solution, temperature, time allowed for binding, concentration of non-related molecules (e.g., serum albumin, milk casein), etc. Exemplary conditions are set forth in Example 4.

[054] The term "TGF-β superfamily" refers to a family of structurally -related growth factors, all of which are endowed with physiologically important growth-regulatory and morphogenetic properties. This family of related growth factors is well known in the art (Kingsley et al. (1994) Genes Dev., 8: 133-146; Hoodless et al. (1998) Curr. Topics Microbiol. Immunol., 228: 235-272). The TGF-β superfamily includes Bone Morphogenetic Proteins (BMPs), Activins, Inhibins, Mullerian Inhibiting Substance, Glial-Derived Neurotrophic Factor, and a still growing number of Growth and Differentiation Factors (GDFs), such as GDF-8 (myostatin). Many of these proteins are related in structure to GDF-8, such as BMP-11; and/or activity, such as activin.

[055] The term "treatment" refers to both therapeutic treatment and prophylactic or preventative measures. Those in need of treatment may

include individuals already having a particular medical disorder as well as those who may ultimately acquire the disorder (*i.e.*, those needing preventative measures).

Detailed Description of the Invention

<u>Antibodies</u>

[056] Intact antibodies are usually heterotetrameric glycoproteins of about 150,000 daltons, composed of two identical light (L) chains and two identical heavy (H) chains. Each light chain is linked to a heavy chain by one covalent disulfide bond, while the number of disulfide linkages varies among the heavy chains of different immunoglobulin isotypes. Each heavy and light chain also has regularly spaced intrachain disulfide bridges. Each heavy chain has at one end a variable domain (V_H) followed by a number of constant domains. Each light chain has a variable domain at one end (V_L) and a constant domain at its other end; the constant domain of the light chain is aligned with the first constant domain of the heavy chain, and the light-chain variable domain is aligned with the variable domain of the heavy chain. Particular amino acid residues are believed to form an interface between the light- and heavy-chain variable domains (Clothia *et al.* (1985) *J. Mol. Biol.*, 186: 651-663; Novotny and Haber (1985) *Proc. Natl. Acad. Sci. USA*, 82: 4592-4596).

[057] Depending on the amino acid sequence of the constant domain of their heavy chains, immunoglobulins can be assigned to different classes. There are five major classes of immunoglobulins: IgA, IgD, IgE, IgG, and IgM, and

several of these may be further divided into subclasses (isotypes), e.g., IgA1

and IgA2 for IgA; IgG1, IgG2, IgG3, IgG4 for IgG in humans, and IgG1, IgG2a,

IgG2b, and IgG3 for IgG in mouse. The heavy-chain constant domains that

correspond to the major classes of immunoglobulins are called α, δ, ϵ, γ, and

μ, respectively. The subunit structures and three-dimensional configurations

of different classes of immunoglobulins are well known in the art.

[058] For a review of the antibody structure, see Antibodies: A Laboratory

Manual, Cold Spring Harbor Laboratory, eds. Harlow et al., 1988. Briefly,

each light chain is composed of an N-terminal variable (V) domain (V_L) and a

constant (C) domain (C_L). Each heavy chain is composed of an N-terminal V

domain, three or four C domains, and a hinge region. The C_H domain most

proximal to V_H is designated as C_H1. The V_H and V_L domain consist of four

regions of relatively conserved sequence called framework regions (FR1,

FR2, FR3, and FR4), which form a scaffold for three regions of hypervariable

sequence (complementarity determining regions, CDRs). The CDRs contain

most of the residues responsible for specific interactions with the antigen.

CDRs are referred to as CDR1, CDR2, and CDR3. Accordingly, CDR

constituents on the on the heavy chain are referred to as H1, H2, and H3,

while CDR constituents on the light chain are referred to as L1, L2, and L3.

CDR3 is the greatest source of molecular diversity within the antibody-binding

site. H3, for example, can be as short as two amino acid residues or greater

than 26. The locations of immunoglobulin variable domains in a given

antibody may be determined as described, for example, in Sequences of

Proteins of Immunological Interest, US Department of Health and Human

Services, eds. Kabat *et al.*, 1991.

[059] Antibody diversity is created by the use of multiple germline genes

encoding variable regions and a variety of somatic events. The somatic

events include recombination of variable gene segments with diversity (D) and

joining (J) gene segments to make a complete V_H region and the

recombination of variable and joining gene segments to make a complete V_L

region. The recombination process itself is imprecise, resulting in the loss or

addition of amino acids at the V(D)J junctions. These mechanisms of

diversity occur in the developing B cell prior to antigen exposure. After

antigenic stimulation, the expressed antibody genes in B cells undergo

somatic mutation. Based on the estimated number of germline gene

segments, the random recombination of these segments, and random V_H-V_L

pairing, up to 1.6×10^7 different antibodies could be produced (Fundamental

Immunology, 3rd ed., ed. Paul, Raven Press, New York, NY, 1993). When

other processes which contribute to antibody diversity (such as somatic

mutation) are taken into account, it is thought that upwards of 1×10^{10} different

antibodies could be generated (Immunoglobulin Genes, 2nd ed., eds. Jonio *et*

al., Academic Press, San Diego, CA, 1995). Because of the many processes

involved in generating antibody diversity, it is unlikely that independently

derived monoclonal antibodies with the same antigen specificity will have

identical amino acid sequences.

[060] Antibodies may be raised against any portion of a protein which provides an antigenic epitope. In one embodiment of the invention, the presently disclosed antibodies specifically bind to an epitope on a protein belonging to the superfamily of TGF-β proteins. The protein is optionally a Bone Morphogenetic Proteins (BMP), Activin, Inhibin, Mullerian Inhibiting Substance, Glial-Derived Neurotrophic Factor, or Growth and Differentiation Factors (GDFs). Optionally, the protein is BMP-11, Activin, or GDF-8. The protein is optionally a mature GDF-8 protein.

[061] In an embodiment, the presently disclosed antibodies bind to a mature GDF-8 protein as set forth in SEQ ID NO:15; optionally between amino acid 1 and amino acid 50; optionally between amino acid 1 and amino acid 25; and optionally between amino acid 1 and 15 of SEQ ID NO:15.

[062] In another embodiment, the presently disclosed antibodies specifically bind to the sequence Asp-Glu-His-Xaa-Thr (SEQ ID NO:2) in any one of the proteins belonging to the TGF-β superfamily, where Xaa is Ala, Gly, His, Met, Asn, Arg, Ser, Thr, or Trp. Optionally, the antibodies specifically bind to the peptide sequence Asp-Glu-His-Xaa-Thr (SEQ ID NO:2) in GDF-8, where Xaa is Ala, Gly, His, Met, Asn, Arg, Ser, Thr, or Trp. Optionally, the antibodies specifically bind to Asp-Glu-His-Ser-Thr (SEQ ID NO:3) in the mature GDF-8 protein (SEQ ID NO:15).

[063] Optionally, the presently disclosed antibodies specifically bind to the peptide sequence
Asp-Phe-Gly-Leu-Asp-Cys-Asp-Glu-His-Xaa-Thr-Glu-Ser-Arg-Cys (SEQ ID

NO:5) in any one of the proteins belonging to the TGF-β superfamily, where

Xaa is Ala, Gly, His, Met, Asn, Arg, Ser, Thr, or Trp. Optionally, the

antibodies specifically bind to the peptide sequence

Asp-Phe-Gly-Leu-Asp-Cys-Asp-Glu-His-Xaa-Thr-Glu-Ser-Arg-Cys (SEQ ID

NO:5) in GDF-8, where Xaa is Ala, Gly, His, Met, Asn, Arg, Ser, Thr, or Trp.

Optionally, the antibodies specifically bind to the peptide sequence

Asp-Phe-Gly-Leu-Asp-Cys-Asp-Glu-His-Ser-Thr-Glu-Ser-Arg-Cys (SEQ ID

NO:8) in the mature GDF-8 protein (SEQ ID NO:15).

[064]   The GDF-8 protein to which the presently disclosed antibodies may

specifically bind is optionally at least about 75%-80% identical to SEQ ID

NO:15, optionally at least about 81% to about 85% identical to SEQ ID NO:15,

optionally at least about 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, or 94%

identical to SEQ ID NO:15, and optionally at least about 95%, 96%, 97%,

98%, 99% or 100% identical to SEQ ID NO:15. The GDF-8 protein optionally

comprises SEQ ID NO:15.

[065]   In an alternative embodiment, the presently disclosed antibodies may

specifically bind to the BMP-11 protein. The BMP-11 protein is optionally at

least about 75%-80% identical to SEQ ID NO:16, optionally at least about

81% to about 85% identical to SEQ ID NO:16, optionally at least about 86%,

87%, 88%, 89%, 90%, 91%, 92%, 93%, or 94% identical to SEQ ID NO:16,

and optionally at least about 95%, 96%, 97%, 98%, 99% or 100% identical to

SEQ ID NO:16. The BMP-11 protein optionally comprises SEQ ID NO:16.

[066] In a particular embodiment, termed JA-16, the antibody comprises the amino acid sequence of SEQ ID NO: 1 as a part of the variable region of the heavy chain. In other embodiments, the antibody comprises at least one single chain CDR chosen from the amino acids 30-35 of SEQ ID NO:1, amino acids 50-66 of SEQ ID NO:1, and amino acids 99-102 of SEQ ID NO:1.

[067] One of skill in the art will recognize that the antibodies of the invention may contain any number of conservative or non-conservative changes to their respective amino acid sequences without altering their biological properties. Changes can be made in either the framework (FR) or in the CDR regions. While changes in the framework regions are usually designed to improve stability and immunogenicity of the antibody, changes in the CDRs are usually designed to increase affinity of the antibody for its target. Such affinity-increasing changes are typically determined empirically by altering the CDR region and testing the antibody. Such alterations can be made according to the methods described in Antibody Engineering, 2nd. ed., Oxford University Press, ed. Borrebaeck, 1995. Conservative amino acid modifications are based on the relative similarity of the amino acid side-chain substituents, for example, their hydrophobicity, hydrophilicity, charge, size, and the like. Exemplary conservative substitutions which take various of the foregoing characteristics into consideration are well known to those of skill in the art and include: arginine and lysine; glutamate and aspartate; serine and threonine; glutamine and asparagine; and valine, leucine, and isoleucine. Further details on such changes are described in the following sections. Unlike in CDRs, more substantial non-conservative changes in structure

framework regions (FRs) can be made without adversely affecting the binding

properties of an antibody. Changes to FRs include, but are not limited to,

humanizing a non-human derived framework or engineering certain

framework residues that are important for antigen contact or for stabilizing the

binding site, *e.g.*, changing the class or subclass of the constant region,

changing specific amino acid residues which might alter an effector function

such as Fc receptor binding (Lund *et al.* (1991) J. Immun. 147: 2657-2662

and Morgan *et al.* (1995) Immunology 86: 319-324), or changing the species

from which the constant region is derived as described below.

[068] In an embodiment, the presently disclosed antibodies specifically bind

to mature GDF-8 protein, regardless of whether it is in monomeric form, active

dimer form, or complexed in a GDF-8 latent complex, with an affinity of

between about 10^6 and about 10^{11} M^{-1}, optionally between about 10^8 and

about 10^{11} M^{-1}.

[069] The antibodies of the present invention may comprise polyclonal

antibodies, monoclonal antibodies, antibody compositions, antibodies having

mono- or poly-specificity, humanized antibodies, single-chain antibodies,

CDR-grafted antibodies, antibody fragments such as Fab, $F(ab')_2$, Fv, and

other antibody fragments which retain the antigen binding function of the

parent antibody. The presently disclosed antibodies may also be modified to

chimeric antibodies. For instance, a human Fc region can be fused to a

GDF-8 binding region from a murine antibody to generate a chimeric antibody.

By replacing other portions of the murine antibody (outside of the antigen

binding region) with corresponding human antibody fragments, a humanized

antibody may be produced. Such chimeric or humanized antibodies may

display enhanced biological specificity or *in vivo* stability. They are

particularly useful in designing antibodies for human therapies. It is

understood that practitioners are familiar with the standard resource materials

which describe specific conditions and procedures for the construction,

manipulation, production, and isolation of antibodies (*see*, for example,

Harlow and Lane (1988) *Antibodies: A Laboratory Manual,* Cold Spring

Harbor Press, Cold Spring Harbor, New York).

[070] The present invention also provides cells, such as hybridomas, that

produce any of the presently disclosed antibodies. One of skill in the art is

familiar with the many cells that are suitable for producing antibodies. Any

cell compatible with the present invention may be used to produce the

presently disclosed antibodies. In an embodiment, the presently disclosed

antibodies are produced by a hybridoma cell. A hybridoma cell line, which

produces murine anti-GDF-8 JA-16 antibody has been deposited with

American Tissue Culture Collection (Deposit Designation Number PTA-4236)

on April 18, 2002. The address of the depository is 10801 University Blvd,

Manassas, VA 20110.

Methods of Treating Disease

[071] The antibodies of the present invention are useful to prevent, diagnose,

or treat various medical disorders in humans or animals. The antibodies are

used to inhibit or reduce one or more activities associated with the GDF

protein, relative to a GDF protein not bound by the same antibody. Optionally, the antibodies inhibit or reduce one or more of the activities of mature GDF-8 (regardless of whether in monomeric form, active dimeric form, or complexed in a GDF-8 latent complex) relative to a mature GDF-8 protein that is not bound by the same antibodies. In an embodiment, the activity of the mature GDF-8 protein, when bound by one or more of the presently disclosed antibodies, is inhibited at least 50%, optionally at least 60, 62, 64, 66, 68, 70, 72, 72, 76, 78, 80, 82, 84, 86, or 88%, optionally at least 90, 91, 92, 93, or 94%, and optionally at least 95% to 100% relative to a mature GDF-8 protein that is not bound by one or more of the presently disclosed antibodies.

[072] The medical disorder being diagnosed, treated, or prevented by the presently disclosed antibodies is optionally a muscle and neuromuscular disorder; an adipose tissue disorder such as obesity; type 2 diabetes, impaired glucose tolerance, metabolic syndromes (*e.g.*, syndrome X), insulin resistance induced by trauma such as burns; or bone degenerative disease such as osteoporosis. The medical condition is optionally a muscle or neuromuscular disorder, such as muscular dystrophy, muscle atrophy, congestive obstructive pulmonary disease, muscle wasting syndrome, sarcopenia, or cachexia and disorders associated with a loss of bone, which include osteoporosis, especially in the elderly and/or postmenopausal women, glucocorticoid-induced osteoporosis, osteopenia, and osteoporosis-related fractures. Other target metabolic bone diseases and disorders amendable to treatment with GDF-8 antibodies of the invention include low bone mass due to chronic glucocorticoid therapy, premature gonadal failure, androgen

suppression, vitamin D deficiency, secondary hyperparathyroidism, nutritional deficiencies, and anorexia nervosa. The antibodies are optionally used to prevent, diagnose, or treat such medical disorders in mammals, optionally in humans.

[073] The antibodies or antibody compositions of the present invention are administered in therapeutically effective amounts. As used herein, an "effective amount" of the antibody is a dosage which is sufficient to reduce the activity of GDF proteins to achieve a desired biological outcome (e.g., increasing muscle mass or strength). Generally, a therapeutically effective amount may vary with the subject's age, condition, and sex, as well as the severity of the medical condition in the subject. The dosage may be determined by an physcian and adjusted, as necessary, to suit observed effects of the treatment. Generally, the compositions are administered so that antibodies are given at a dose between 1 µg/kg and 20 mg/kg. Optionally, the antibodies are given as a bolus dose, to maximize the circulating levels of antibodies for the greatest length of time after the dose. Continuous infusion may also be used after the bolus dose.

[074] The methods of treating, diagnosing, or preventing the above medical conditions with the presently disclosed antibodies can also be used on other proteins in the TGF-β superfamily. Many of these proteins, e.g., BMP-11, are related in structure to GDF-8. Accordingly, in another embodiment, the invention provides methods of treating the aforementioned disorders by administering to a subject an antibody capable of inhibiting BMP-11 or activin,

either alone or in combination with other TGF-β inhibitors, such as a neutralizing antibody against GDF-8.

[075]   The antibodies of the present invention may be used to detect the presence of proteins belonging to the TGF-β superfamily, such as BMP-11 and GDF-8. By correlating the presence or level of these proteins with a medical condition, one of skill in the art can diagnose the associated medical condition. The medical conditions that may be diagnosed by the presently disclosed antibodies are set forth above.

[076]   Such detection methods are well known in the art and include ELISA, radioimmunoassay, immunoblot, western blot, immunofluorescence, immuno-precipitation, and other comparable techniques. The antibodies may further be provided in a diagnostic kit that incorporates one or more of these techniques to detect a protein (e.g., GDF-8). Such a kit may contain other components, packaging, instructions, or other material to aid the detection of the protein and use of the kit.

[077]   Where the antibodies are intended for diagnostic purposes, it may be desirable to modify them, for example with a ligand group (such as biotin) or a detectable marker group (such as a fluorescent group, a radioisotope or an enzyme). If desired, the antibodies (whether polyclonal or monoclonal) may be labeled using conventional techniques. Suitable labels include fluorophores, chromophores, radioactive atoms, electron-dense reagents, enzymes, and ligands having specific binding partners. Enzymes are typically detected by their activity. For example, horseradish peroxidase is usually

detected by its ability to convert 3,3',5,5'-tetramethylbenzidine (TMB) to a blue

pigment, quantifiable with a spectrophotometer. Other suitable labels include,

for example, one of the binding partners such as biotin and avidin or

streptavidin, IgG and protein A, and various receptor-ligand couples known in

the art. Other permutations and possibilities will be readily apparent to those

of ordinary skill in the art, and are considered as equivalents within the scope

of the instant invention.

Antibody Compositions

[078] The present invention provides compositions comprising the presently

disclosed antibodies. Such compositions may be suitable for pharmaceutical

use and administration to patients. The compositions typically comprise one

or more antibodies of the present invention and a pharmaceutically

acceptable excipient. As used herein, the phrase "pharmaceutically

acceptable excipient" includes any and all solvents, dispersion media,

coatings, antibacterial and antifungal agents, isotonic and absorption delaying

agents, and the like, that are compatible with pharmaceutical administration.

The use of such media and agents for pharmaceutically active substances is

well known in the art. The compositions may also contain other active

compounds providing supplemental, additional, or enhanced therapeutic

functions. The pharmaceutical compositions may also be included in a

container, pack, or dispenser together with instructions for administration.

[079] A pharmaceutical composition of the invention is formulated to be

compatible with its intended route of administration. Methods to accomplish

the administration are known to those of ordinary skill in the art. It may also be possible to obtain compositions which may be topically or orally administered, or which may be capable of transmission across mucous membranes. The administration may, for example, be intravenous, intraperitoneal, intramuscular, intracavity, subcutaneous or transdermal.

[080] Solutions or suspensions used for intradermal or subcutaneous application typically include one or more of the following components: a sterile diluent such as water for injection, saline solution, fixed oils, polyethylene glycols, glycerine, propylene glycol or other synthetic solvents; antibacterial agents such as benzyl alcohol or methyl parabens; antioxidants such as ascorbic acid or sodium bisulfite; chelating agents such as ethylenediaminetetraacetic acid; buffers such as acetates, citrates or phosphates; and agents for the adjustment of tonicity such as sodium chloride or dextrose. The pH can be adjusted with acids or bases, such as hydrochloric acid or sodium hydroxide. Such preparations may be enclosed in ampoules, disposable syringes or multiple dose vials made of glass or plastic.

[081] Pharmaceutical compositions suitable for injection include sterile aqueous solutions or dispersions and sterile powders for the extemporaneous preparation of sterile injectable solutions or dispersion. For intravenous administration, suitable carriers include physiological saline, bacteriostatic water, Cremophor EL™ (BASF, Parsippany, NJ) or phosphate buffered saline (PBS). In all cases, the composition must be sterile and should be fluid to the

extent that easy syringability exists. It must be stable under the conditions of manufacture and storage and must be preserved against the contaminating action of microorganisms such as bacteria and fungi. The carrier can be a solvent or dispersion medium containing, for example, water, ethanol, polyol (for example, glycerol, propylene glycol, and liquid polyetheylene glycol, and the like), and suitable mixtures thereof. The proper fluidity can be maintained, for example, by the use of a coating such as lecithin, by the maintenance of the required particle size in the case of dispersion and by the use of surfactants. Prevention of the action of microorganisms can be achieved by various antibacterial and antifungal agents, for example, parabens, chlorobutanol, phenol, ascorbic acid, thimerosal, and the like. In many cases, isotonic agents, for example, sugars, polyalcohols such as manitol, sorbitol, sodium chloride will be included in the composition. Prolonged absorption of the injectable compositions can be brought about by including in the composition an agent which delays absorption, for example, aluminum monostearate and gelatin.

[082] Oral compositions generally include an inert diluent or an edible carrier. They can be enclosed in gelatin capsules or compressed into tablets. For the purpose of oral therapeutic administration, the antibodies can be incorporated with excipients and used in the form of tablets, troches, or capsules. Pharmaceutically compatible binding agents, and/or adjuvant materials can be included as part of the composition. The tablets, pills, capsules, troches, and the like can contain any of the following ingredients, or compounds of a similar nature; a binder such as microcrystalline cellulose, gum tragacanth or gelatin;

an excipient such as starch or lactose, a disintegrating agent such as alginic acid, Primogel, or corn starch; a lubricant such as magnesium stearate or Sterotes; a glidant such as colloidal silicon dioxide; a sweetening agent such as sucrose or saccharin; or a flavoring agent such as peppermint, methyl salicylate, or orange flavoring.

[083] For administration by inhalation, the antibodies are delivered in the form of an aerosol spray from pressured container or dispenser which contains a suitable propellant, *e.g.*, a gas such as carbon dioxide, or a nebulizer.

[084] Systemic administration can also be by transmucosal or transdermal means. For transmucosal or transdermal administration, penetrants appropriate to the barrier to be permeated are used in the formulation. Such penetrants are generally known in the art, and include, for example, for transmucosal administration, detergents, bile salts, and fusidic acid derivatives. Transmucosal administration can be accomplished through the use of nasal sprays or suppositories. For transdermal administration, the active compounds are formulated into ointments, salves, gels, or creams as generally known in the art.

[085] The antibodies may also be prepared in the form of suppositories (e.g., with conventional suppository bases such as cocoa butter and other glycerides) or retention enemas for rectal delivery.

[086]   In one embodiment, the presently disclosed antibodies are prepared with carriers that will protect the compound against rapid elimination from the body, such as a controlled release formulation, including implants and microencapsulated delivery systems. Biodegradable, biocompatible polymers can be used, such as ethylene vinyl acetate, polyanhydrides, polyglycolic acid, collagen, polyorthoesters, and polylactic acid. Methods for preparation of such formulations will be apparent to those skilled in the art. The materials can also be obtained commercially from Alza Corporation and Nova Pharmaceuticals, Inc. Liposomal suspensions containing the presently disclosed antibodies can also be used as pharmaceutically acceptable carriers. These can be prepared according to methods known to those skilled in the art, for example, as described in U.S. Patent No. 4,522,811.

[087]   It is especially advantageous to formulate oral or parenteral compositions in dosage unit form for ease of administration and uniformity of dosage. Dosage unit form as used herein refers to physically discrete units suited as unitary dosages for the subject to be treated; each unit containing a predetermined quantity of active compound calculated to produce the desired therapeutic effect in association with the required pharmaceutical carrier. The specification for the dosage unit forms of the invention are dictated by and directly dependent on the unique characteristics of the active compound and the particular therapeutic effect to be achieved, and the limitations inherent in the art of compounding such an active compound for the treatment of individuals.

[088] Toxicity and therapeutic efficacy of such compounds can be determined by standard pharmaceutical procedures in cell cultures or experimental animals, *e.g.*, for determining the LD_{50} (the dose lethal to 50% of the population) and the ED_{50} (the dose therapeutically effective in 50% of the population). The dose ratio between toxic and therapeutic effects is the therapeutic index and it can be expressed as the ratio LD_{50}/ED_{50}. Antibodies which exhibit large therapeutic indices are an embodiment of the invention.

[089] The data obtained from the cell culture assays and animal studies can be used in formulating a range of dosage for use in humans. The dosage of such compounds lies optionally within a range of circulating concentrations that include the ED_{50} with little or no toxicity. The dosage may vary within this range depending upon the dosage form employed and the route of administration utilized. For any antibody used in the present invention, the therapeutically effective dose can be estimated initially from cell culture assays. A dose may be formulated in animal models to achieve a circulating plasma concentration range that includes the IC_{50} (*i.e.*, the concentration of the test antibody which achieves a half-maximal inhibition of symptoms) as determined in cell culture. Levels in plasma may be measured, for example, by high performance liquid chromatography. The effects of any particular dosage can be monitored by a suitable bioassay. Examples of suitable bioassays include DNA replication assays, transcription-based assays, GDF protein/receptor binding assays, creatine kinase assays, assays based on the differentiation of pre-adipocytes, assays based on glucose uptake in adipocytes, and immunological assays.

Modified Antibodies

[090] It is understood by one of ordinary skill in the art that certain amino acids may be substituted for other amino acids in a protein structure without adversely affecting the activity of the protein, *e.g.*, binding characteristics of an antibody. It is thus contemplated by the inventors that various changes may be made in the amino acid sequences of the presently disclosed antibodies, or DNA sequences encoding the antibodies, without appreciable loss of their biological utility or activity. Such changes may include deletions, insertions, truncations, substitutions, fusions, shuffling of motif sequences, and the like.

[091] In making such changes, the hydropathic index of amino acids may be considered. The importance of the hydropathic amino acid index in conferring interactive biological function on a protein is generally understood in the art (Kyte and Doolittle (1982) *J. Mol. Biol.*, 157: 105-132). It is accepted that the relative hydropathic character of the amino acid contributes to the secondary structure of the resultant protein, which in turn defines the interaction of the protein with other molecules, for example, enzymes, substrates, receptors, DNA, antibodies, antigens, and the like.

[092] Each amino acid has been assigned a hydropathic index on the basis of its hydrophobicity and charge characteristics (Kyte and Doolittle, 1982); these are isoleucine (+4.5), valine (+4.2), leucine (+3.8), phenylalanine (+2.8), cysteine/cystine (+2.5), methionine (+1.9), alanine (+1.8), glycine (-0.4), threonine (-0.7), serine (-0.8), tryptophan (-0.9), tyrosine (-1.3), proline (-1.6),

histidine (-3.2), glutamate (-3.5), glutamine (-3.5), aspartate (-3.5), asparagine (-3.5), lysine (-3.9), and arginine (-4.5).

[093] In making such changes, the substitution of amino acids whose hydropathic indices are within ±2 is an embodiment of the invention, those which are within ±1 are optional, and those within ±0.5 are also optional.

[094] It is also understood in the art that the substitution of like amino acids can be made effectively on the basis of hydrophilicity. U.S. Patent 4,554,101 states that the greatest local average hydrophilicity of a protein, as govern by the hydrophilicity of its adjacent amino acids, correlates with a biological property of the protein.

[095] As detailed in U.S. Patent 4,554,101, the following hydrophilicity values have been assigned to amino acid residues: arginine (+3.0), lysine (+3.0), aspartate (+3.0±1), glutamate (+3.0±1), serine (+0.3), asparagine (+0.2), glutamine (+0.2), glycine (0), threonine (-0.4), proline (-0.5±1), alanine (-0.5), histidine (-0.5), cysteine (-1.0), methionine (-1.3), valine (-1.5), leucine (-1.8), isoleucine (-1.8), tyrosine (-2.3), phenylalanine (-2.5), and tryptophan (-3.4).

[096] In making such changes, the substitution of amino acids whose hydrophilicity values are within ±2 is an embodiment of the invention, those within ±1 are optional, and those within ±0.5 are optional.

[097] The modifications may be conservative such that the structure or biological function of the protein is not affected by the change. Such

conservative amino acid modifications are based on the relative similarity of

the amino acid side-chain substituents, for example, their hydrophobicity,

hydrophilicity, charge, size, and the like. Exemplary conservative ·

substitutions which take various of the foregoing characteristics into

consideration are well known to those of skill in the art and include: arginine

and lysine; glutamate and aspartate; serine and threonine; glutamine and

asparagine; and valine, leucine, and isoleucine. The amino acid sequence of

the presently disclosed antibodies may be modified to have any number of

conservative changes, so long as the binding of the antibody to its target

antigen is not adversely affected. Such changes may be introduced inside or

outside of the antigen binding portion of the antibody. For example, changes

introduced inside of the antigen binding portion of the antibody may be

designed to increase the affinity of the antibody for its target.

[098] In addition to the changes to the amino acid sequence outlined above,

the antibodies can be glycosylated, pegylated, or linked to albumin or a

nonproteinaceous polymer. For instance, the presently disclosed antibodies

may be linked to one of a variety of nonproteinaceous polymers, e.g.,

polyethylene glycol, polypropylene glycol, or polyoxyalkylenes, in the manner

set forth in U.S. Patent Numbers 4,640,835; 4,496,689; 4,301,144; 4,670,417;

4,791,192; or 4,179,337. The antibodies are chemically modified by covalent

conjugation to a polymer to increase their circulating half-life, for example.

Certain polymers, and methods to attach them to peptides, are also shown in

U.S. Pat. Nos. 4,766,106; 4,179,337; 4,495,285; and 4,609,546.

[099] In another embodiment, the antibody may be modified to have an altered glycosylation pattern (*i.e.*, altered from the original or native glycosylation pattern). As used herein, "altered" means having one or more carbohydrate moieties deleted, and/or having one or more glycosylation sites added to the original antibody.

[0100] Glycosylation of antibodies is typically either N-linked or O-linked. N-linked refers to the attachment of the carbohydrate moiety to the side chain of an asparagine residue. The tripeptide sequences asparagine-X-serine and asparagine-X-threonine, where X is any amino acid except proline, are the recognition sequences for enzymatic attachment of the carbohydrate moiety to the asparagine side chain. Thus, the presence of either of these tripeptide sequences in a polypeptide creates a potential glycosylation site. O-linked glycosylation refers to the attachment of one of the sugars N-aceylgalactosamine, galactose, or xylose to a hydroxyamino acid, most commonly serine or threonine, although 5-hydroxyproline or 5-hydroxylysine may also be used.

[0101] Addition of glycosylation sites to the presently disclosed antibodies is conveniently accomplished by altering the amino acid sequence such that it contains one or more of the above-described tripeptide sequences (for N-linked glycosylation sites). The alteration may also be made by the addition of, or substitution by, one or more serine or threonine residues to the sequence of the original antibodies (for O-linked glycosylation sites). For

ease, the antibody amino acid sequence is optionally altered through changes at the DNA level.

[0102] Another means of increasing the number of carbohydrate moieties on the antibodies is by chemical or enzymatic coupling of glycosides to the amino acid residues of the antibody. These procedures are advantageous in that they do not require production of the GDF peptide inhibitor in a host cell that has glycosylation capabilities for N- or O-linked glycosylation. Depending on the coupling mode used, the sugars may be attached to (a) arginine and histidine, (b) free carboxyl groups, (c) free sulfhydryl groups such as those of cysteine, (d) free hydroxyl groups such as those of serine, threonine, or hydroxyproline, (e) aromatic residues such as those of phenylalanine, tyrosine, or tryptophan, or (f) the amide group of glutamine. These methods are described in WO 87/05330, and in Aplin and Wriston (1981) *CRC Crit. Rev. Biochem.*, 22: 259-306.

[0103] Removal of any carbohydrate moieties present on the antibodies may be accomplished chemically or enzymatically. Chemical deglycosylation requires exposure of the antibody to trifluoromethanesulfonic acid, or an equivalent compound. This treatment results in the cleavage of most or all sugars except the linking sugar (N-acetylglucosamine or N-acetylgalactosamine), while leaving the amino acid sequence intact.

[0104] Chemical deglycosylation is described by Hakimuddin *et al.* (1987) *Arch. Biochem. Biophys.*, 259: 52; and Edge *et al.* (1981) *Anal. Biochem.*, 118: 131. Enzymatic cleavage of carbohydrate moieties on GDF peptide

inhibitors can be achieved by the use of a variety of endo- and

exo-glycosidases as described by Thotakura *et al.* (1987) *Meth. Enzymol.*,

138: 350.

Sequence Analysis

[0105] While not always necessary, if desired, one of ordinary skill in the art

may determine the amino acid or nucleic acid sequences of the presently

disclosed antibodies. The present invention includes these amino acid and

nucleic acid sequences. The present invention also include variants,

homologues, and fragments of these nucleic and amino acid sequences. For

example, the antibody may comprise a heavy chain variable region sequence

that comprises SEQ ID NO:1, or a nucleic acid sequence that encodes SEQ

ID NO:1 (*e.g.*, SEQ ID NO:6). The nucleic or amino acid sequence optionally

comprises a sequence at least 70% to 79% identical to the nucleic or amino

acid sequence of the presently disclosed variable heavy chain region,

optionally at least 80% to 89% identical, optionally at least 90% to 95%

identical, and optionally at least 96% to 100% identical. One of skill in the art

will recognize that the CDR region, which determines the antigenic binding

properties of the antibody, can tolerate less sequence variation than the other

portions of the antibody not involved in antigen binding. Thus, these

non-binding regions of the antibody may contain substantial variations without

significantly altering the binding properties of the antibody. However, one of

skill in the art will also recognize that many changes can be made to the CDR

region that are specifically designed to increase the affinity of the antibody for

its target. Such affinity-increasing changes are typically determined empirically by altering the CDR region and testing the antibody. All such alterations, whether within the CDR or outside the CDR, are included in the scope of the present invention.

[0106] Relative sequence similarity or identity may be determined using the "Best Fit" or "Gap" programs of the Sequence Analysis Software Package™ (Version 10; Genetics Computer Group, Inc., University of Wisconsin Biotechnology Center, Madison, WI). "Gap" utilizes the algorithm of Needleman and Wunsch (Needleman and Wunsch, 1970) to find the alignment of two sequences that maximizes the number of matches and minimizes the number of gaps. "BestFit" performs an optimal alignment of the best segment of similarity between two sequences. Optimal alignments are found by inserting gaps to maximize the number of matches using the local homology algorithm of Smith and Waterman (Smith and Waterman, 1981; Smith *et al.*, 1983).

[0107] The Sequence Analysis Software Package described above contains a number of other useful sequence analysis tools for identifying homologues of the presently disclosed nucleotide and amino acid sequences. For example, the "BLAST" program (Altschul *et al.*, 1990) searches for sequences similar to a query sequence (either peptide or nucleic acid) in a specified database (*e.g.*, sequence databases maintained at the National Center for Biotechnology Information (NCBI) in Bethesda, MD); "FastA" (Lipman and Pearson, 1985; *see also* Pearson and Lipman, 1988; Pearson *et al.*, 1990)

performs a Pearson and Lipman search for similarity between a query sequence and a group of sequences of the same type (nucleic acid or protein); "TfastA" performs a Pearson and Lipman search for similarity between a protein query sequence and any group of nucleotide sequences (it translates the nucleotide sequences in all six reading frames before performing the comparison); "FastX" performs a Pearson and Lipman search for similarity between a nucleotide query sequence and a group of protein sequences, taking frameshifts into account. "TfastX" performs a Pearson and Lipman search for similarity between a protein query sequence and any group of nucleotide sequences, taking frameshifts into account (it translates both strands of the nucleic sequence before performing the comparison).

[0108]   The following examples provide embodiments of the invention. One of ordinary skill in the art will recognize the numerous modifications and variations that may be performed without altering the spirit or scope of the present invention. Such modifications and variations are believed to be encompassed within the scope of the invention. The examples do not in any way limit the invention.

[0109]   The entire contents of all references, patents and published patent applications cited throughout this application are herein incorporated by reference.

EXAMPLES

<u>Example 1:   Purification of GDF-8</u>

[0110]   Conditioned media from a selected cell line expressing full-length

human GDF-8 protein (mature GDF-8 + GDF-8 propeptide) were acidified to

pH 6.5 and applied to a 80 x 50 mm POROS HQ anion exchange column in

tandem to a 80 x 50 mm POROS SP cation exchange column (PerSeptive

Biosystems, Foster City, CA). The flow through was adjusted to pH 5.0 and

applied to a 75 x 20 mm POROS SP cation exchange column (PerSeptive

Biosystems) and eluted with a NaCl gradient. Fractions containing the

GDF-8, as indicated by sodium dodecyl sulfate polyacrylamide gel

electrophoresis (SDS-PAGE), were pooled, acidified with trifluoroacetic acid

(TFA) to pH 2-3, then brought up to 200 ml with 0.1% TFA to lower the

viscosity. The pool was then applied to a 250 x 21.2 mm C_5 column

(Phenomenex, Torrance, CA) preceded by a 60 x 21.2 mm guard column

(Phenomenex) and eluted with a TFA/CH$_3$CN gradient, to separate mature

GDF-8 from GDF-8 propeptide. Pooled fractions containing mature GDF-8

were concentrated by lyophilization to remove the acetonitrile and 20 ml of

0.1% TFA was added. The sample was then applied to a 250 x 10 mm C_5

column (Phenomenex) heated to 60°C to aid in separation. This was

repeated until further separation could no longer be achieved. Fractions

containing mature GDF-8 were then pooled and brought up to 40%

acetonitrile and applied to a 600 x 21.2 BioSep S-3000 size exclusion column

(Phenomenex) preceded by a 60 x 21.2 guard column. Fractions containing

purified mature GDF-8 were pooled and concentrated for use in subsequent experiments.

[0111]   C5 column fractions containing GDF-8 propeptide were pooled, the acetonitrile was removed by evaporation, 20 ml of 0.1% TFA was added, and the sample was then injected onto the 250 x 10 mm C5 column at 60°C. This was repeated until further separation could no longer be achieved. Fractions containing the GDF-8 propeptide were then pooled and brought up to 40% acetonitrile and applied to a 600 x 21.2 BioSep S-3000 size exclusion column (Phenomenex) preceded by a 60 x 21.2 guard column. Fractions containing the purified GDF-8 propeptide were pooled and concentrated for use in subsequent experiments.

[0112]   On SDS-PAGE, purified mature GDF-8 migrated as a broad band at 25 kDa under nonreducing conditions and 13 kDa under reducing conditions. A similar SDS-PAGE profile has been reported for murine GDF-8 (McPherron et al., 1997, supra), and reflects the dimeric nature of the mature protein.

[0113]   The apparent molecular weight of purified GDF-8 propeptide was 38 kDa under both reducing and nonreducing conditions. This indicates that the GDF-8 propeptide by itself is monomeric. The difference between the apparent molecular weight and the predicted molecular weight of GDF-8 propeptide, ~ 26 kDa, may reflect the addition of carbohydrate, since its amino acid sequence contains a potential N-linked glycosylation site (McPherron et al., 1997, supra).

Example 2:　Characteristics of Purified Recombinant Human GDF-8

[0114]　50 μg each of purified mature GDF-8 and purified GDF-8 propeptide were mixed and dialyzed into 50 mM sodium phosphate, pH 7.0, and chromatographed on a 300 x 7.8 mm BioSep S-3000 size exclusion column (Phenomenex).　Molecular weight of the mature GDF-8:propeptide complex was determined from elution time, using molecular weight standards (Bio-Rad Laboratories, Hercules, CA) chromatographed on the same column.

[0115]　When purified GDF-8 propeptide was incubated with purified mature GDF-8 at neutral pH, the two proteins appeared to complex, as indicated by the size exclusion profile.　The primary protein peak eluted at 12.7 minutes had an estimated molecular weight of 78 kDa from molecular weight standards (Bio-Rad Laboratories, Hercules, CA) chromatographed on the same column.　The size of the complex is most consistent with one dimer of the mature GDF-8 associating with two monomers of propeptide.

[0116]　To confirm this observation, a preparation containing both mature GDF-8 and GDF-8 propeptide was incubated with or without 100 mM 1-Ethyl 3-(3-dimethylaminopropyl)carbodiimide hydrochloride (EDC, Pierce) for 1 hour at room temperature (RT), acidified with HCl to pH 2-3, and concentrated with a Micron-10 Amicon concentrator (Millipore, Bedford, MA) for SDS-PAGE, using a tricine buffered 10% acrylamide gel.　Proteins were visualized by Coomassie blue staining of the gel.　In the presence of EDC, a cross-linked complex with an apparent molecular weight of 75 kDa was observed.

[0117]   The GDF-8 propeptide DNA and amino acid sequence are set forth

in McPherron and Lee (1997) *Proc. Natl. Acad. Sci. USA*, 94: 12457-12461.

Example 3:   Production of anti-GDF-8 Antibody

[0118]   To develop an antibody capable of inhibiting GDF-8 activity, a group

of GDF-8 knockout mice were immunized every two weeks with mature

GDF-8 protein (purified as described in Example 1) mixed in Freunds

complete adjuvant for the first two immunizations, and incomplete Freunds

adjuvant thereafter. Throughout the immunization period, blood was sampled

and tested for the presence of circulating antibodies. At week 9, an animal

with circulating antibodies was selected, immunized for three consecutive

days, and sacrificed. The spleen was removed and homogenized into cells.

The spleen cells were fused to a myeloma fusion partner (line

P3-x63-Ag8.653) using 50% PEG 1500 by an established procedure (Oi &

Herzenberg (1980) *Selected Methods in Cellular Immunology*, W. J. Freeman

Co., San Francisco, CA, p. 351). The fused cells were plated into 96-well

microtiter plates at a density of 2×10^5 cells/well. After 24 hours, the cells

were subjected to HAT selection (Littlefield (1964) *Science*, 145: 709)

effectively killing any unfused and unproductively fused myeloma cells.

[0119]   Successfully fused hybridoma cells secreting anti-GDF-8 antibodies

were identified by solid and solution phase ELISAs. Mature GDF-8 protein

was prepared from CHO cells as described above and coated on polystyrene

(for solid phase assays) or biotinylated (for a solution based assay).

Neutralizing assays were also employed where the ActRIIB receptor was

coated on a polystyrene plate and biotin GDF-8 binding was inhibited by the

addition of hybridoma supernatant. Results identified hybridomas expressing

GDF-8 antibodies. These positive clones were cultured and expanded for

further study. These cultures remained stable when expanded and cell lines

were cloned by limiting dilution and cryopreserved.

[0120]   From these cell cultures, a panel of antibodies was developed that

specifically recognize mature GDF-8. Isotype of the antibodies was

determined using a mouse immunoglobulin isotyping kit (Zymed Laboratories,

San Francisco, CA). One of the antibody clones, designated JA-16, was

studied further.

Example 4: Characterization of JA-16 Binding Specificity

[0121]   To determine the binding specificity of JA-16, a panel of synthetic

peptides corresponding to portions of the GDF-8 protein sequence was

produced. Fig. 1 shows the GDF-8 synthetic peptides used in this study.

Even number peptides (N2-N14) were biotinylated on the primary amine. The

biotinylated peptides N2, N4, N6, N8, N10, N12, N14, and an irrelevant

peptide DAE-10, were coated at 1 µg/ml for 2 hrs at room temperature on

Reacti-Bind™ Streptavidin coated polystyrene 96 well plates (Pierce,

Rockford, IL, Cat. No.15124) following the manufacturer's protocol.

[0122]   After blocking, JA-16 or a unrelated monoclonal antibody control was

added to the ELISA plate at 100, 10, and 1 nM (JA-16 only), and incubated for

30 min. After washing the plate, a secondary antibody (goat anti-murine IgG

(H+L)-HRP, Calbiochem, San Diego, CA, Cat. No. 401215) was added at a

1:1000 dilution and incubated for 30 minutes at room temperature. The plate

was washed four times, and TMB substrate was added (KPL, Gaithersburg,

MD, Cat. No. 50-76-04). Colorimetric measurements were done at 450 nm in

a Molecular Devices microplate reader. The results are shown in Fig. 2.

JA-16 bound strongly and specifically to the biotinylated N-terminal peptide

N8 (SEQ ID NO:65).

[0123]   Mature GDF-8 and BMP-11 are 90% homologous at the amino acid

level (Fig. 3). Three of these changes are present within the N8 peptide. To

compare the specificity of JA-16 towards GDF-8 and BMP-11, shorter

peptides were designed G1 and B1 specific for GDF-8 and BMP-11,

respectively. Differences between G1 and B1 are indicated with underlining.

[0124]   G1:

Asp-Phe-Gly-Leu-Asp-Ser-Asp-Glu-His-Ser-Thr-Glu-Ser-Arg-Cys (SEQ ID

NO:10)

[0125]   B1:

Asn-Leu-Gly-Leu-Asp-Ser-Asp-Glu-His-Ser-Ser-Glu-Ser-Arg-Cys (SEQ ID

NO:9)

[0126]   The peptides G1 and B1 were conjugated to BSA using a PIERCE

conjugation kit (Cat. No. 77116ZZ) following manufacturer's protocol.

G1-BSA and B1-BSA were coated on 96 well flat-bottom assay plates

(Costar, NY, Cat. No. 3590) at 1 µg/ml in 0.2 M sodium carbonate buffer

overnight at 4°C. The plates were washed and blocked with PBS, 1 mg/ml

BSA, 0.05 % Tween for 1 hour at room temperature. JA-16 (5 nM) was

serially diluted (1:2). The dilutions were added to the ELISA plate and

incubated for 30 min at RT. After 4 washes, a secondary antibody (goat

anti-murine IgG (H+L)-HRP, Calbiochem, Cat. No. 401215) was added at a

1:1000 dilution and incubated for 30 min at RT. Plates were washed four

times, and TMB substrate was added (KPL, Cat. No. 50-76-04). Colorimetric

measurements were done at 450 nm in a Molecular Devices microplate

reader. Fig. 4 shows that JA-16 binds to G1-BSA in a concentration

dependent manner, but not to B1-BSA, even at the highest concentration.

[0127]   To look further into JA-16 specificity, G1-BSA was coated as

described above, but this time, JA-16 at 5 nM was preincubated with either

G1 peptide or B1 peptide, GDF-8, or BMP-11 at various concentrations. The

result is shown in Fig. 5. The BMP-11 specific peptide B1 does not inhibit

binding of JA-16 to G1-BSA, but G1 does. The IC_{50} for GDF-8 is 0.8 µg/ml,

while BMP-11's IC_{50} is 3.8 µg/ml demonstrating that JA-16 recognizes GDF-8

with a 5-fold higher affinity than BMP-11.

Example 5:   Mapping of JA-16 Epitope

[0128]   In order to map the exact epitope of JA-16, overlapping 13-mer

peptides (SEQ ID NOS:17-64, *see* Fig. 6A) corresponding to portions of the

GDF-8 sequence were synthesized directly on cellulose paper using the spot

synthesis technique (Molina *et al.* (1996) *Peptide Research,* 9: 151-155;

Frank *et al.* (1992) *Tetrahedron,* 48: 9217-9232). In this array, cysteine

residues were replaced with serine in order to reduce the chemical

complications that are caused by the presence of cysteines. Cellulose

membranes modified with polyethylene glycol and Fmoc-protected amino

acids were purchased from Abimed (Lagenfeld, Germany). The array was

defined on the membrane by coupling a β-alanine spacer and peptides were

synthesized using standard DIC (diisopropylcarbodiimide)/HOBt

(hydroxybenzotriazole) coupling chemistry as described previously (Molina *et*

al. (1996) *Peptide Research*, 9: 151-155; Frank *et al.* (1992) *Tetrahedron*, 48:

9217-9232).

[0129]   Activated amino acids were spotted using an Abimed ASP 222

robot. Washing and deprotection steps were done manually and the peptides

were N-terminally acetylated after the final synthesis cycle. Following peptide

synthesis, the membrane was washed in methanol for 10 minutes and in

blocker (TBST (Tris buffered saline with 0.1% (v/v) Tween 20) + 1% (w/v)

casein) for 10 minutes. The membrane was then incubated with 2.5 µg/ml

JA-16 in blocker for 1 hour with gentle shaking. After washing with blocker 3

times for 10 minutes, the membrane was incubated with HRP-labeled

secondary antibody (0.25 µg/ml in blocker) for 30 minutes. The membrane

was then washed 3 times for 10 minutes each with blocker and 2 times for 10

minutes each with TBST. Bound antibody was visualized using SuperSignal

West reagent (Pierce) and a digital camera (AlphaInnotech FluorImager).

Results are shown in Fig. 6B. JA-16 bound to the first 4 peptides of the array

(SEQ ID NOS:17-20), which corresponds to 18 residues on the N-terminus of

GDF-8.

[0130]   In order to further characterize the JA-16 epitope, deletion and

substitution analyses of the peptide

Gly-Leu-Asp-Ser-Asp-Glu-His-Ser-Thr-Glu-Ser-Arg-Ser (SEQ ID NO:18) were

performed using spot synthesis. In the substitution analysis, each residue of

this peptide was individually replaced with each of the 20 natural amino acids

except cysteine, generating SEQ ID NOS: 3, 18, 66-104, 106-113, and

115-128. Synthesis and binding assays were performed as described above.

The results are shown in Fig. 7. Substitutions in the 4 N-terminal amino acids

and the 4 C-terminal amino acids were well tolerated, suggesting that these

amino acids were not needed for JA-16 binding to mature GDF-8. However,

no changes were tolerated in the middle segment of this peptide,

Asp-Glu-His-Ser-Thr (SEQ ID NO:3), except for a few substitutions at the

serine residue, suggesting that this peptide sequence was required for JA-16

binding. In addition, the sequence Asp-Glu-His-Ser-Thr (SEQ ID NO:3) was

the smallest peptide to which binding could be detected in the deletion

analysis. Thus, the results suggest that JA-16 recognizes the epitope

Asp-Glu-His-Ser-Thr (SEQ ID NO:3) in GDF-8, with the Asp, Glu, His and Thr

residues (Asp-Glu-His-Xaa-Thr (SEQ ID NO:2)) being important for binding.

Example 6:   Characterization of JA-16 *In Vitro*

[0131]   Two assays were performed to determine the ability of JA-16 to

neutralize GDF-8 activity *in vitro*. First, JA-16 was tested for its ability to

inhibit mature GDF-8 protein binding to the ActRIIB receptor. Recombinant

ActRIIB.Fc chimera (R&D Systems, Minneapolis, MN, Cat. No. 339-RB/CF)

was coated on 96 well flat-bottom assay plates (Costar, Cat. No. 3590) at 1

µg/ml in 0.2 M sodium carbonate buffer overnight at 4°C. Plates were then

blocked with 1 mg/ml bovine serum albumin and washed following standard

ELISA techniques.

[0132]   100 µl of biotinylated mature GDF-8 protein at various

concentrations was added to the blocked ELISA plates, incubated for 1 hour,

and washed. The amount of bound mature GDF-8 protein was detected by

'streptavidin-horseradish peroxidase (SA-HRP, BD PharMingen, San Diego,

CA, Cat. No. 13047E) followed by the addition of TMB (KPL, Cat. No.

50-76-04). Colorimetric measurements were done at 450 nm in a Molecular

Devices microplate reader. The results are shown in Fig. 8. The mature

GDF-8 exhibited an ED_{50} of 12 ng/ml.

[0133]   The same protocol was also performed after preincubating the JA-16

antibody with biotinylated mature GDF-8 protein at 5 ng/ml for 30 min. An

irrelevelant monoclonal antibody was included as a negative control. Fig. 9

shows that JA-16 has a very weak *in vitro* neutralizing activity of around 1 µM.

This *in vitro* data suggests that JA-16 is unlikely to be a very good neutralizer

of active GDF-8, particularly under less controlled *in vivo* conditions.

[0134]   In a second set of assays, a reporter gene assay was performed to

assess the biological activity of active GDF-8 protein *in vitro*. The assay uses

a reporter vector, pGL3(CAGA)$_{12}$, coupled to luciferase. The CAGA sequence

was previously reported to be a TGF-β -responsive sequence within the

promoter of the TGF-β -induced gene, PAI-1.

[0135]   The reporter vector containing 12 CAGA boxes was made using the

basic reporter plasmid, pGL3 (Promega Corporation, Madison, WI, Cat. No.

E1751). The TATA box and transcription initiation site from the adenovirus

major late promoter (-35/+10) was inserted between the $BglII$ and $HindIII$

sites. Oligonucleotides containing twelve repeats of the CAGA boxes

AGCCAGACA were annealed and cloned into the $XhoI$ site. The human

rhabdomyosarcoma cell line, A204 (ATCC HTB-82), was transiently

transfected with pGL3(CAGA)$_{12}$ using FuGENE 6 transfection reagent (Roche

Diagnostics, Indianapolis, MN Cat. No. 1 814 443). Following transfection,

cells were cultured on 48 well plates in McCoys 5A medium (Life

Technologies, Rockville, MD, Cat. No. 21500-079) supplemented with 2 mM

glutamine, 100 U/ml streptomycin, 100 µg/ml penicillin and 10% fetal calf

serum for 16 h. Cells were then treated with mature GDF-8, BMP-11, or

activin in McCoy's 5A media with glutamine, streptomycin, penicillin, and 1

mg/ml bovine serum albumin for 6 h at 37°C. Luciferase was quantified in the

treated cells using the Luciferase Assay System (Promega Corporation,

Madison, WI, Cat. No. E1483). GDF-8 maximally activated the reporter

construct 10-fold, with an ED_{50} of 10 ng/ml GDF-8. BMP-11, which is 90%

identical to GDF-8 at the amino acid level (Gamer *et al.* (1999) *Dev. Biol.*,

208(1): 222-32; Nakashima *et al.* (1999) *Mech. Dev.*, 80(2): 185-9), and

activin elicited a similar biological response.

[0136]   JA-16's neutralizing activity was determined by preincubating JA-16

with mature GDF-8 protein for 30 min prior to addition to the A204 cells. An

irrelevant antibody (monoclonal control) as well as a human GDF-8 antibody

derived from scFv phagemid library using phage display technology (Myo-19) were also tested.

[0137]   Fig. 10 shows that, in this assay as well, JA-16 is weakly neutralizing with an IC_{50} of around 1 µM, while the Myo-19 IC_{50} is around 100 nM. Based on this *in vitro* data, one would have expected the Myo-19 antibody to be a better neutralizer of active GDF-8 protein than JA-16 *in vivo*, which is not the case, as shown herein.

Example 7:   Immunoprecipitation of GDF-8 with JA-16

[0138]   In order to evaluate the binding of JA-16 to mature GDF-8 and GDF-8 complexes, a series of immunoprecipitation studies were conducted.

[0139]   First, to determine if JA-16 can immunoprecipitate the GDF-8 latent complex, CHO cells expressing GDF-8 were radiolabeled with ^{35}S-methionine and ^{35}S-cysteine. 100 µl of conditioned medium from these cells containing GDF-8 latent complex was incubated with 1 mg/ml JA-16 for 1 hour at 4°C. Protein A Sepharose was added to the mixture, which was then incubated overnight at 4°C. The immunoprecipitate was collected, washed three times with a PBS/Triton-X100 buffer, resuspended in reducing sample buffer and analyzed by SDS-PAGE. The gel was fixed overnight, enhanced with autoradiography enhancer solution, dried and the autoradiogram was developed. Figure 18, lane 2, shows that JA-16 can immunoprecipitate the GDF-8 latent complex and unprocessed GDF-8.

[0140]   Second, to determine if JA-16 can immunoprecipitate a complex

formed between GDF-8 and follistatin, CHO cells expressing follistatin were

radiolabeled with ^{35}S-methionine and ^{35}S-cysteine. 100 µl of conditioned

medium containing radiolabeled follistatin was mixed with mature GDF-8 to

form a complex of GDF-8 with follistatin. The mixture was incubated with 1

mg/ml JA-16 for 1 hour at 4°C. Protein A Sepharose was added to the

mixture, which was then incubated overnight at 4°C. The immunoprecipitate

was collected and analyzed as described above. Figure 18, lane 6, shows

that JA-16 can co-immunoprecipitate labeled follistatin complexed with

GDF-8.

[0141]   Third, to investigate whether JA-16 can immunoprecipitate mature

GDF-8 protein, conditioned media from CHO cells containing radiolabeled

GDF-8 latent complex was acid activated to dissociate the GDF-8 propeptide

and mature GDF-8 (see van Waarde et al. (1997) Analytical Biochemistry,

247, 45-51). This material was then incubated with JA-16 for 1 hour at 4°C.

The remainder of the protocol was performed as described above. Figure 18,

lane 3, shows that JA-16 can immunoprecipitate mature GDF-8.

[0142]   The results indicate that JA-16 can recognize the GDF-8 latent

complex, the GDF-8:follistatin complex, and mature GDF-8. In contrast,

Myo-19 cannot bind any GDF-8 complexes (Fig. 18, lanes 4 and 7) and can

only immunoprecipitate mature GDF-8 (Fig. 18, lane 5).

Example 8:   Characterization of JA-16 *In Vivo*

[0143]   In order to determine if the antibody JA-16 increases muscle mass in

adult mice, an *in vivo* study was conducted with seven-week-old female

BALB/c mice. Mice were weighed and evenly distributed with respect to body

weight into groups of seven or eight. JA-16 in PBS or an isotype matched

antibody to snake venom (control) was injected into the mice intraperitoneally

at 50 mg/kg twice weekly. The treatment continued for four weeks. Animals

were assessed for gain in lean body mass by subjecting them to dexascan

analysis before and after the treatment period. Muscle mass was assessed

by dissecting and weighing the gastrocnemius and quadriceps. The

peri-uterine fat pad was also removed and weighed. The results of this study

indicated that JA-16 significantly inhibits GDF-8 activity *in vivo* resulting in

increased muscle mass (Fig. 11).

[0144]   A longer study was also performed in which the antibodies were

administered intraperitoneally at 60 mg/kg/week for 14 weeks. These mice

were loaded at the beginning of the study with 60 mg/kg intraperitoneally and

10 mg/kg intravenously. The mice in this study were male C57BL mice that

were either wild type at the agouti locus (a) or carried the lethal yellow

mutation (Ay) at that locus. The Ay mutation causes adult onset obesity and

diabetes, which allowed us to determine the effect of JA-16 on muscle,

excess fat, and blood glucose in a diabetic background. Total body mass was

measured weekly (Fig. 12). Muscle mass was assessed by dissecting and

weighing the gastrocnemius and quadriceps (Fig. 13). The epididymal and

inguinal fat pads were also removed and weighed (Fig. 14). Twelve weeks

into the study, the mice were fasted and blood glucose levels were measured

(Fig. 15). As with the four week study, the results of this study indicate that

JA-16 inhibits GDF-8 activity *in vivo* causing an increase in muscle mass. In

addition, this study indicates that in obese and diabetic mice, inhibition of

GDF-8 leads to improved levels of blood glucose.

[0145] The *in vivo* activity of JA-16 was also compared to the *in vivo* activity

of another GDF-8 antibody, Myo-19. C57B6/scid mice we injected

intraperitoneally for five weeks with vehicle control or with 60 mg/kg loading

dose plus 60 mg/kg per week of JA-16 or Myo-19. Total body mass was

measured weekly and muscle mass was assessed by dissecting and

weighing the gastrocnemius and quadriceps (Fig. 17). While five weeks of

treatment with JA-16 led to an increase in muscle mass, treatment with

Myo-19 did not effect muscle mass. In another experiment, Myo-19 treatment

was extended to 10 and to 15 weeks, and no increase in body mass or

muscle mass was seen for these time points.

[0146] Thus, despite the fact that the *in vitro* data suggested that JA-16 was

a weaker neutralizer than Myo-19, the mouse studies clearly, but

unexpectedly, demonstrate that JA-16 effectively reduces GDF-8 activity *in*

vivo while Myo-19 does not. These results indicate that the specific site on

GDF-8 to which JA-16 binds is unique in that this site is responsible for the

formation of a stable inhibitory GDF-8:antibody complex *in vivo*. Thus, it is

expected that any antibody specifically binding site, as identified in Example 4, will possess *in vivo* neutralizing properties similar to or better than JA-16.

Example 9:   JA-16 Increases Muscle Strength

[0147]   In humans, muscle size and strength decreases by approximately 1% per year starting in the third decade of life. For many aged people, the loss in muscle mass is significantly debilitating. This condition is known as sarcopenia, or age related loss of muscle. In order to determine if anti-GDF-8 treatment is effective for sarcopenia, aged mice (19 months of age at the beginning of the study and 21 months of age at the end of the study) were treated with JA-16 for 8 weeks at 60 mg/kg once a week. In the same experiment, young mice (2 month of age at the beginning of the study and 4 months of age at the end of the study) were treated with the same dose of JA-16. At the end of the study, both groups of mice had greater muscle mass than the vehicle treated controls as seen, for example, from the quadriceps mass comparison (Fig. 19A).

[0148]   In order to confirm that the increase in muscle size leads to an increase in muscle strength, we performed grip strength tests with aged and young mice treated with JA-16 for eight weeks using a meter purchased from Columbia Instruments (Columbus, Ohio; model 1027csx). Mice were allowed to grip and pull on the grid, and the peak force of the pull was recorded. Untrained mice were tested five times in succession without rest. The peak

force for each test was recorded and the results of the five tests were averaged for each mouse. After seven weeks of treatment, the peak force for the young JA-16 treated mice was 10% greater and for the aged JA-16 treated mice was 13% greater than the peak force for vehicle treated mice (Fig. 19B). In addition, longitudinal measurements taken before and after 7 weeks of treatment showed that strength of the aged mice increased by 17% (p < 0.01) with JA-16 treatment, while the strength of the vehicle treated aged mice was not significantly changed (3.3%, p = 0.66). These results confirm that GDF-8 inhibition leads to an increase in muscle size *and* strength in both young and aged mice and that it may be a useful therapy for sarcopenia.

Example 10: JA-16 Increases Muscle Mass and Strength in Dystrophic Muscle

[0149]   The ability of *in vivo* inhibition of GDF-8 to ameliorate muscular dystrophy was tested in the *mdx* mouse model of Duchenne's muscular dystrophy (DMD). The DMD model has been described, for example, by Torres *et al.* (*Brain* (1987) 110, 269-299) and Hoffman *et al.* (*Science* (1987) 238, 347-350).

[0150]   Four week old male *mdx* mice were treated with weekly intraperitoneal injections of JA-16 (60 mg/kg), and vehicle alone (control group) for 3 months. To quantify the increase of muscle mass, animals were sacrificed and extensor digitorum longus (EDL) muscles dissected out and weighed. As shown in Figure 20A, EDL muscles from the treated group of

animals weighed significantly more than controls. Of note, the relative

increase in muscle mass was greater than the increase in body weight as

shown in Figure 20B. Consistently with this data, other muscle groups

including the gastrocnemius, tibialis anterior and quadriceps were found to

have similar increases in weight.

[0151]   To quantify the absolute force production or muscle strength, we

recorded the maximal isometric force produced upon depolarization of muscle

using field electrodes. Figures 20C and 20D show that the JA-16 treated *mdx*

mice were able to exert a significantly higher maximal force during either

twitch or tetanus. The increase in muscle strength was proportional to the

increase in muscle mass (Figures 20A, 20C, and 20D). These results offer

physiological evidence for predicted therapeutic efficacy of GDF-8 inhibitors

such as JA-16 in treatment of muscular dystrophy and related diseases.

[0152]   To independently verify the amelioration of the dystrophic phenotype

observed in the *mdx* diaphragms, as well as ascertain improvement in the

pathological status of *mdx* skeletal musculature *in toto*, we analyzed serum

Creatine kinase (CK) levels from these mice. Extremely high levels of CK are

consistently noted with dystrophin-deficiency in *mdx* mice and humans due to

sarcolemmal damage (Bulfield et al. (1984) *Proc. Natl. Acad. Sci. USA* 81,

1189-1192 and Matsuda et al. (1995) *J. Biochem. (Tokyo)* 118, 959-64). At

the start of the trial both the treated and control groups of *mdx* mice had

marked elevations of serum CK compared to normal mice. However, after

three months of *in vivo* myostatin blockade there was a dramatic decline in

serum CK levels of treated *mdx* mice (Figure 4c). The decrease in muscle

degeneration and fibrosis coupled with reduction of CK offers histological and

biochemical evidence for a functional improvement in *mdx* muscle produced

by myostatin blockade *in vivo*.

Example 11: *In Vivo* Role of GDF-8 in Trabecular Bone

[0153]   Increased mechanical loading, either due to increased muscle activity

or increased body weight, is associated with increased bone mass and bone

density. Therefore, GDF-8 knockout (KO) mice were assessed for altered

bone mass and microarchitecture. An initial assessment of adult mice

showed that bone density in the spine of the KO mice was nearly two-fold

higher than that of their wild-type littermates. This increase far exceeded

what might have been expected to be solely due to the increased muscle

mass in the GDF-8 KO mice.

[0154]   High resolution microtomographic imaging (µCT40, Scanco Medical,

Switzerland) was used to assess the trabecular bone volume fraction and

microarchitecture in the 5th lumbar vertebrae and distal femora and cortical

bone geometry at the femoral mid-diaphysis of adult GDF-8 wildtype (WT)

and KO mice. Specimens were taken from 9-10 month old GDF-8 male and

female KO and littermate controls (four mice of each genotype and sex). The

entire vertebral body and femur were scanned using microcomputed

tomography at 12 µm resolution. Regions of interest encompassing the

trabecular bone of the vertebral body or the trabecular bone of the distal

femoral metaphysis (*i.e.*, secondary spongiosa) were identified using a

- 62 -

semi-automated contouring algorithm. The following parameters were computed using direct 3D assessments: bone volume fraction (%), trabecular thickness (µm), separation (µm) and number (1/mm). In addition, the connectivity density, an indicator of how well the trabecular network is connected, was assessed as well as cortical bone parameters at the middiaphyseal region in the femur, including total area, bone area, and cortical thickness.

[0155] Both male and female KO mice had dramatically increased trabecular bone density in the vertebral body compared to WT littermates (n=4, +93% and +70%, respectively, p<0.0001). This increased trabecular bone density was accompanied by a 14% increase in trabecular thickness (p=0.03), a 38% increase in trabecular number (p=0.0002), and a 10% decrease in trabecular separation (p=0.009). The combined effect of these changes in architecture and density resulted in a 3.4- and 1.7-fold increase in connectivity in male and female KO, respectively, compared to their WT littermates (p<0.0001). In addition, a rough measure of the level of mineralization of the trabecular bone indicated that the average mineral content of the trabeculae was 8% higher in the KO mice relative to the controls (p<0.0001). There is a hint that the effect is larger in male than female mice, but the sample size is too small to make definitive conclusions. Vertebral trabecular bone characteristics assessed by high-resolution microcomputed tomography are shown in Table 1.

[0156] In contrast to observations in the spine, male and female KO mice had lower trabecular bone density in the distal femur than WT littermates

(n=4, p=0.05 for overall genotype effect) (Table 2). This decrement in bone density was more pronounced in female KO than in male KO mice. GDF-8 KO mice had similar trabecular thickness as their WT littermates, but had fewer trabeculae and increased trabecular separation compared to littermate controls. However, although cortical thickness at the femoral midshaft was similar in male GDF-8 KO and their littermate controls, it was approximately 10% greater in the GDF-8 KO female mice than their WT littermates (n=4, p=0.04) (see Table 3). There were no differences in cortical bone area or bone area fraction between the two genotypes.

TABLE 1: Vertebral Trabecular Bone Characteristics (mean ± SEM)

	Male WT	**Male KO**	**Female WT**	**Female KO**
Bone volume fraction (%)	23.3 ± 4.7	45.0 ± 5.5	27.5 ± 5.5	46.9 ± 10.8
Trabecular thickness (µm)	52 ± 3	58 ± 6	52 ± 5	61 ± 8
Trabecular separation (µm)	210 ± 21	145 ± 8	183 ± 21	169 ± 41
Trabecular number (1/mm)	4.6 ± 0.4	7.0 ± 0.4	5.2 ± 0.4	6.6 ± 1.3
Connectivity density (1/mm³)	137 ± 15	470 ± 114	198 ± 29	339 ± 81
Degree of anisotropy	1.68 ± 0.08	1.29 ± 0.02	1.54 ± 0.12	1.34 ± 0.03

Bone Area/Total Area (%)	353 ± 16	472 ± 90	296 ± 73	464 ± 98

Example 12: Treatment of Muscle and Bone Degenerative Disorders

[0157] Inhibitors of GDF-8, such as, for example inhibitory antibodies, are useful for treatments directed at increased muscle mass, and also for prevention and treatment of osteoporosis. In addition, inhibition of GDF-8 may be useful in other instances where a bone anabolic effect is desired, such as augmentation of bone healing (i.e., fracture repair, spine fusion, etc.). The anti-GDF-8 antibodies of the invention are used to treat a subject at disease onset or having an established muscle or bone degenerative disease.

[0158] Efficacy of anti-GDF-8 antibodies for treatment of bone disorders, e.g., osteoporosis, is confirmed using well established models of osteoporosis. For example, ovariectomized mice have been used to test the efficacy of new osteoporosis drug treatments (Alexander et al. (2001) *J. Bone Min. Res.* 16: 1665-1673; and Anderson et al. (2001) *J. Endocrinol.* 170:529-537). Similar to humans, these rodents exhibit a rapid loss of bone following ovariectomy, especially in cancellous bone. Outcome assessments are based on bone mineral density, biochemical markers of bone turnover in serum and urine, bone strength, and histology/histomorphometry.

[0159] In one study, normal and/or immune compromised female mice are ovariectomized at 12-16 weeks of age and allowed to lose bone for four to six weeks. Following this bone loss period, treatment with an anti-GDF-8 antibody such as JA-16 (IP injection) or vehicle is conducted for one to six months. The treatment protocol could vary, with testing of different doses and treatment regimens (e.g., daily, weekly, or bi-weekly injections). It is anticipated that untreated ovariectomized mice (or rats) would lose approximately 10-30% of bone density relative to intact (i.e., non-ovariectomized), age-matched mice. It is anticipated that mice treated with the anti-GDF-8 antibody would have 10 to 50% greater bone mass and bone density than those mice receiving placebo, and moreover that this increase in bone density would be associated with increased bone strength, particularly in regions with a greater proportion of cancellous bone compared to cortical bone.

[0160]   The goal of another study is to demonstrate that anti-GDF-8 antibody such as JA-16 is effective in preventing the decline in bone mass, microarchitecture and strength associated with estrogen deficiency. Thus, the study has a similar design to the one described above, except that treatment with anti-GDF-8 antibody would be initiated immediately after ovariectomy, rather than after the bone loss period. It is anticipated that mice treated with the antibody would lose significantly less bone mass following ovariectomy than mice treated with vehicle.

[0161]   The inhibitory antibodies against GDF-8 are also used to prevent and/or to reduce severity and/or the symptoms of the disease. It is anticipated that the anti-GDF-8 antibodies would be administered as a subcutaneous injection as frequently as once per day and as infrequently as once per month. Treatment duration could range between one month and several years.

[0162]   To test the clinical efficacy of anti-GDF-8 in humans, postmenopausal women with low bone mass are identified by bone density testing and randomized to a treatment group. Treatment groups include a placebo group and one to three groups receiving antibody (different doses). Individuals are followed prospectively for one to three years to assess changes in biochemical markers of bone turnover, changes in bone mineral density, and the occurrence of fragility fractures. It is anticipated that individuals receiving treatment would exhibit an increase in bone mineral density in the proximal femur and lumbar spine of 2-30% relative to baseline, and would have a

decreased incidence of fragility fractures. It is anticipated that biochemical markers of bone formation would increase.

[0163]   The antibodies are administered as the sole active compound or in combination with another compound or composition. When administered as the sole active compound or in combination with another compound or composition, the dosage may be between approximately 1 µg/kg and 20 mg/kg, depending on the severity of the symptoms and the progression of the disease. The appropriate effective dose is selected by a treating clinician from the following ranges: 1 µg/kg and 20 mg/kg, 1 µg/kg and 10 mg/kg, 1 µg/kg and 1 mg/kg, 10 µg/kg and 1 mg/kg, 10 µg/kg and 100 µg/kg, 100 µg and 1 mg/kg, and 500 µg/kg and 1 mg/kg. Exemplary treatment regimens and outcomes are summarized in Table 4.

TABLE 4: Examples of Clinical Cases

Patient No.	Status prior to treatment	Treatment Regimen	Outcome
Patient 1	No clinical signs, postmenopausal and/or over 60 years old	0.01–1 mg/kg biweekly for 4-24 weeks	Maintenance and/or increase of muscle/bone mass
Patient 2	Mild clinical signs, muscle wasting and/or bone loss	0.01–20 mg/kg weekly for 4 more weeks	Maintenance and/or increase of muscle/bone mass
Patient 3	Advanced stage of osteoporosis	0.01–20 mg/kg twice weekly for 6 or more weeks	Improvement of clinical signs, maintenance and/or increase of muscle/bone mass
Patient 4	Severe muscle and bone loss	0.01–20 mg/kg daily for 6 or more weeks	Improvement of clinical signs, reduction in severity of symptoms and/or increase of muscle/bone mass

Example 13: Treatment of Metabolic Disorders

[0164]   Inhibitors of GDF-8, such as, for example inhibitory antibodies, are useful for treatment of metabolic disorders such as type 2 diabetes, impaired glucose tolerance, metabolic syndrome (e.g., syndrome X), insulin resistance induced by trauma (e.g., burns), and adipose tissue disorders (e.g., obesity). The anti-GDF-8 antibodies of the invention are used to treat a subject at disease onset or having an established metabolic disease.

[0165]   Efficacy of anti-GDF-8 antibodies for treatment of metabolic disorders, e.g., type 2 diabetes and/or obesity, is confirmed using well established murine models of obesity, insulin resistance and type 2 diabetes, including ob/ob, db/db, and strains carrying the lethal yellow mutation. Insulin resistance can also be induced by high fat or high caloric feeding of certain strains of mice including, C57BL/6J. Similar to humans, these rodents develop insulin resistance, hyperinsuliemia, dyslipidemia, and deterioration of glucose homeostasis resulting in hyperglycemia. Outcome assessments are based on serum measurements of glucose, insulin, and lipids. Improved insulin sensitivity can be determined by insulin tolerance tests and glucose tolerance tests. More sensitive techniques would include the use of euglycemic-hyperinsulinemic clamps for assessing improvements is glycemic control and insulin sensitivity. In addition, the clamp techniques would allow a quantitative assessment of the role of the major glucose disposing tissues (e.g., muscle, adipose, and liver) in improved glycemic control.

[0166]   In one study, treatment with an anti-GDF-8 antibody such as JA-16 (IP injection) or vehicle is conducted for one week to six months. The treatment protocol could vary, with testing of different doses and treatment regimens (e.g., daily, weekly, or bi-weekly injections). It is anticipated that mice treated with the anti-GDF-8 antibody would have greater glucose uptake, increased glycolysis and glycogen synthesis, lower free fatty acids and triglycerides in the serum as compared to mice receiving placebo treatment.

[0167]   The inhibitory antibodies against GDF-8 are also used to prevent

and/or to reduce severity and/or the symptoms of the disease. It is

anticipated that the anti-GDF-8 antibodies would be administered as a

subcutaneous injection as frequently as once per day and as infrequently as

once per month. Treatment duration could range between one month and

several years.

[0168]   To test the clinical efficacy of anti-GDF-8 in humans, subjects

suffering from or at risk for type 2 diabetes are identified and randomized to a

treatment group. Treatment groups include a placebo group and one to three

groups receiving antibody (different doses). Individuals are followed

prospectively for one month to three years to assess changes in glucose

metabolism. It is anticipated that individuals receiving treatment would exhibit

an improvement.

[0169]   The antibodies are administered as the sole active compound or in

combination with another compound or composition. When administered as

the sole active compound or in combination with another compound or

composition, the dosage may be between approximately 1 µg/kg and 20

mg/kg, depending on the severity of the symptoms and the progression of the

disease. The appropriate effective dose is selected by a treating clinician

from the following ranges: 1 µg/kg and 20 mg/kg, 1 µg/kg and 10 mg/kg, 1

µg/kg and 1 mg/kg, 10 µg/kg and 1 mg/kg, 10 µg/kg and 100 µg/kg, 100 µg

and 1 mg/kg, and 500 µg/kg and 1 mg/kg. Exemplary treatment regimens and

outcomes are summarized in Table 5.

TABLE 5: Examples of Clinical Cases

Patient No.	Status prior to treatment	Treatment Regimen	Outcome
Patient 1	No clinical signs, family history of type 2 diabetes	0.01–1 mg/kg every 4 weeks for 48 weeks	Prevention of type 2 diabetes
Patient 2	Mild clinical signs of syndrome X	0.01–20 mg/kg weekly for 4 more weeks	Improved insulin tolerance and glucose metabolism, and lower blood pressure
Patient 3	Advanced stage of type 2 diabetes	0.01–20 mg/kg twice weekly for 6 or more weeks	Improvement of clinical signs, reduction in severity of symptoms and/or increase in muscle mass/ body fat ratio
Patient 4	Severe insulin resistance and/obesity	0.01–20 mg/kg daily for 6 or more weeks	Improvement of clinical signs, reduction in severity of symptoms and/or decrease in body fat

We claim:

1. An isolated antibody that specifically binds to a GDF-8 protein, wherein the GDF-8 protein comprises the amino acid sequence Asp-Glu-His-Xaa-Thr (SEQ ID NO:2), wherein Xaa is Ala, Gly, His, Met, Asn, Arg, Ser, Thr, or Trp, and wherein the antibody reduces one or more biological activities associated with the GDF-8 protein, relative to a GDF-8 protein that is not bound by the same antibody.

2. The antibody of claim 1, wherein the antibody binds to the region from amino acid 1 to amino acid 50 of the GDF-8 protein sequence.

3. The antibody of claim 1, wherein the antibody binds to the region from amino acid 1 to amino acid 25 of the GDF-8 protein sequence.

4. The antibody of claim 1, wherein the antibody binds the amino acid sequence Asp-Phe-Gly-Leu-Asp-Cys-Asp-Glu-His-Xaa-Thr-Glu-Ser-Arg-Cys (SEQ ID NO:5) in the GDF-8 protein, where Xaa is Ala, Gly, His, Met, Asn, Arg, Ser, Thr, or Trp.

5. The antibody of claim 1, wherein the antibody binds the amino acid sequence Asp-Phe-Gly-Leu-Asp-Cys-Asp-Glu-His-Ser-Thr-Glu-Ser-Arg-Cys (SEQ ID NO:8) in a GDF-8 protein.

6.   The antibody of claim 1, wherein the antibody binds the amino acid

sequence Asp-Glu-His-Ser-Thr (SEQ ID NO:3) in the GDF-8 protein.

7.   The antibody of claim 1, wherein the GDF-8 protein comprises an

amino acid sequence that is at least 75% identical to SEQ ID NO:15.

8.   The antibody of claim 7, wherein the GDF-8 protein is SEQ ID NO:15.

9.   The antibody of claim 1, wherein the antibody recognizes the GDF-8

latent complex, GDF-8 in complex with follisatin, or GDF-8 in complex

with a follistatin related protein.

10.   The antibody of claim 1, wherein the antibody is a monoclonal

antibody.

11.   The antibody of claim 10, wherein the antibody is the JA-16

monoclonal antibody produced by a cell having ATCC Deposit

Designation Number PTA-4236.

12.   A cell that produces the monoclonal antibody of claim 10.

13.   A pharmaceutical composition comprising the antibody of claim 1.

14.   The composition of claim 13, further comprising a pharmaceutically

acceptable excipient.

15.   A method of treating a patient suffering from a medical disorder,

wherein the patient would therapeutically benefit from an increase in

mass of muscle tissue, comprising: administering to a mammal a

therapeutically effective dose of an antibody that is capable of specifically binding to a GDF-8 protein, wherein the GDF-8 protein comprises the amino acid sequence Asp-Glu-His-Xaa-Thr (SEQ ID NO:2), wherein Xaa is Ala, Gly, His, Met, Asn, Arg, Ser, Thr, or Trp, and wherein the antibody reduces one or more biological activities associated with a GDF-8 protein in the patient, relative to a patient not receiving the same antibody.

16.   The method of claim 15, wherein the antibody binds to the GDF-8 protein in the region from amino acid 1 to amino acid 50 of the GDF-8 protein sequence.

17.   The method of claim 15, wherein the antibody binds to the GDF-8 protein in the region from amino acid 1 to amino acid 25 of the GDF-8 protein sequence.

18.   The method of claim 15, wherein the antibody binds the amino acid sequence Asp-Phe-Gly-Leu-Asp-Cys-Asp-Glu-His-Xaa-Thr-Glu-Ser-Arg-Cys (SEQ ID NO:5) in the GDF-8 protein, where Xaa is Ala, Gly, His, Met, Asn, Arg, Ser, Thr, or Trp.

19.   The method of claim 15, wherein the antibody binds the amino acid sequence Asp-Phe-Gly-Leu-Asp-Cys-Asp-Glu-His-Ser-Thr-Glu-Ser-Arg-Cys (SEQ ID NO:8) in a GDF-8 protein.

20.   The method of claim 15, wherein the antibody binds the amino acid sequence Asp-Glu-His-Ser-Thr (SEQ ID NO:3) in the GDF-8 protein.

21.   The method of claim 15, wherein the GDF-8 protein comprises an amino acid sequence that is at least 75% identical to SEQ ID NO:15.

22.   The method of claim 15, wherein the GDF-8 protein is SEQ ID NO:15.

23.   The method of claim 15, wherein the antibody recognizes the GDF-8 latent complex, GDF-8 in complex with follisatin, or GDF-8 in complex with a follistatin related protein.

24.   The method of claim 15, wherein the antibody is the JA-16 monoclonal antibody produced by a cell having ATCC Deposit Designation Number PTA-4236.

25.   The method of claim 15, wherein the medical disorder is a muscular disorder, neuromuscular disorder, adipose tissue disorder, diabetes, or bone degenerative disorder.

26.   The method of claim 15, wherein the medical disorder is a muscular or neuromuscular disorder.

27.   The method of claim 15, wherein the medical disorder is muscular dystrophy, muscle atrophy, congestive obstructive pulmonary disease, muscle wasting syndrome, sarcopenia, or cachexia.

28.   The method of claim 15, wherein the medical disorder is muscular

        dystrophy.

29.   The method of claim 15, wherein the medical disorder is obesity, type 2

        diabetes, or osteoporosis.

30.   A cell that produces the monoclonal antibody of claim 1.

31.   A nucleic acid encoding the antibody of claim 1.

32.   A diagnostic kit comprising the antibody of claim 1.

33.   An antibody produced by the cell having ATCC Deposit Designation

        Number PTA-4236.

34.   An antibody comprising a heavy chain variable region that comprises

        an amino acid sequence at least 85% identical to SEQ ID NO:1.

35.   The antibody of claim 34, wherein the amino acid sequence is SEQ ID

        NO:1.

36.   A nucleic acid encoding a heavy chain variable region that comprises

        an amino acid sequence at least 85% identical to SEQ ID NO:1.

37.   The nucleic acid of claim 36, wherein the nucleic acid molecule

        comprises SEQ ID NO:6.

38.   An isolated antibody that specifically binds to a protein comprising an

        amino acid sequence as set out in SEQ ID NO:2.

39. The antibody of claim 38, wherein the antibody specifically binds to a protein comprising an amino acid sequence as set out in SEQ ID NO:3.

40. The antibody of claim 38, wherein the antibody specifically binds to a protein comprising an amino acid sequence as set out in SEQ ID NO:5.

41. The antibody of claim 40, wherein the antibody specifically binds to a protein comprising an amino acid sequence as set out in SEQ ID NO:18.

42. The antibody of claim 38, which is made using cell line with ATCC Deposit Designation Number PTA-4236.

43. The antibody of claim 38, comprising at least one single chain CDR chosen from the amino acids 30-35 of SEQ ID NO:1, amino acids 50-66 of SEQ ID NO:1, and amino acids 99-102 of SEQ ID NO:1.

44. A method of increasing muscle mass, said method comprising administering a therapeutically effective amount of the antibody of claim 38 to a mammal, thereby increasing muscle mass.

45. A method of increasing trabecular bone density, said method comprising a administering a therapeutically effective amount of the antibody of claim 38 to a mammal, thereby increasing trabecular bone density.

46. A method of increasing muscle strength, said method comprising administering a therapeutically effective amount of the antibody of claim 38 to a mammal, thereby increasing muscle strength.

47. A nucleic acid encoding antibody of claim 38.

48. A method of inhibiting GDF-8 activity comprising providing the antibody of claim 1 and allowing it to inhibit GDF-8 activity.

49. An isolated antibody that specifically binds to a protein, wherein the protein comprises the amino acid sequence of SEQ ID NO:9.

50. The antibody of claim 49, wherein the protein is BMP-11 or a fragment thereof.

51. The antibody of claim 49, which is made using cell line with ATCC Deposit Designation Number PTA-4236.

52. A method of increasing muscle mass, said method comprising administering a therapeutically effective amount of the antibody of claim 49 to a mammal, thereby increasing muscle mass.

53. A method of increasing trabecular bone density, said method comprising a administering a therapeutically effective amount of the antibody of claim 49 to a mammal, thereby increasing trabecular bone density.

54. A method of increasing muscle strength, said method comprising administering a therapeutically effective amount of the antibody of claim 49 to a mammal, thereby increasing muscle strength.

(19) World Intellectual Property Organization
International Bureau

(43) International Publication Date
3 April 2003 (03.04.2003)

PCT

(10) International Publication Number
WO 03/027248 A3

(54) Title: ANTIBODY INHIBITORS OF GDF-8 AND USES THEREOF

(57) Abstract: The disclosure provides novel antibodies against growth and differentiation factor-8 (GDF-8), including antibody fragments, which inhibit GDF-8 activity in vitro and in vivo. The disclosure also provides methods for diagnosing, preventing, or treating degenerative disorders of muscle, bone, or insulin metabolism.

INTERNATIONAL SEARCH REPORT

A. CLASSIFICATION OF SUBJECT MATTER
IPC(7)   :   A61K 39/395, C07K 16/00
US CL   :   424/158.1; 530/388.1, 389.1

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
U.S. : 424/158.1; 530/388.1, 389.1

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)
Please See Continuation Sheet

C. DOCUMENTS CONSIDERED TO BE RELEVANT		
Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X --- Y	US 6,096,506 A (LEE et al.) 01 August 2000 (01.08.2000), figures 2, 6, and 7, column 16, lines 23-66, and column 17, lines 1-5.	1-10, 12-14, 30-32, 38-41, 47, 48 ---------- 15-23, 25-29, 44-48
X --- Y	5,914,234 A (LEE et al.) 22 June 1999 (22.06.1999), column 9, lines 15-67, column 10, lines 1-4.	49, 50 ---------- 52-54
Y	US 6,004,937 A (WOOD et al.) 21 December 1999 (21.12.1999), column 2, lines 54-67, column 3, lines 1-7.	44-46, 52-54

☐ Further documents are listed in the continuation of Box C.	☐ See patent family annex.

*	Special categories of cited documents:	"T"	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A"	document defining the general state of the art which is not considered to be of particular relevance		
"E"	earlier application or patent published on or after the international filing date	"X"	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"L"	document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"Y"	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"O"	document referring to an oral disclosure, use, exhibition or other means	"&"	document member of the same patent family
"P"	document published prior to the international filing date but later than the priority date claimed		

Date of the actual completion of the international search	Date of mailing of the international search report
24 December 2002 (24.12.2002)	04 FEB 2003
Name and mailing address of the ISA/US Commissioner of Patents and Trademarks Box PCT Washington, D.C. 20231 Facsimile No. (703)305-3230	Authorized officer Janet Andres Telephone No. 703-308-0196
